Metastases of the liver occur in many cases of cancer of the bronchus. The primary tumor is usually small and difficult to discover. These liver metastases often grow rapidly and always involve the whole liver, whereas cancer of the gall-bladder causes metastases only in the right lobe of the liver. In cancer of the stomach and intestine there are also frequently diffuse liver metastases.

The rare primary liver carcinoma is always associated with a tumor of the spleen and early and severe icterus, which is long absent in secondary tumors of the liver. When there are multiple metastases to the bones, one must suspect not only cancer of the bronchus but also cancer of the prostate and multiple myeloma. Metastases of the bronchial cancer in the brain and spinal cord constitute a special chapter. These are often the chief symptoms of the disease and the lung manifestations may be secondary, so that the examiner is inclined to suspect primary disorders of the central nervous system. Nevertheless, a precise examination of the lungs will usually furnish a suggestion, particularly if the possibility of the primary bronchial tumor is kept in mind. The prognosis of all these cases is unfavorable, but not infrequently they take a surprisingly slow course.

## Tuberculosis of the Mediastinal Glands

From observations made at an old people's home in Vienna (6000 beds) during the past ten years Dr Arnstein recently lectured before the Vienna Medical Society on Tuberculosis of the Mediastinal Glands in Aged Persons. In contradistinction to this disease in children which takes the form of swelling

of the lymph nodes, there developed in aged persons a shrinkage and softening of the tissues, inflammations and infections in the region of the bronchi, the esophagus, the blood vessels and the nerves. One observes traction diverticula of the esophagus, bronchitis deformans, paralysis of the recurrent nerve (usually of the left side) and also atypical infiltration processes in the lung, hemoptysis, often quickly fatal, arises from erosion of blood vessels in the bronchi or esophagus, with softening of the lymph nodes. Cases that have come to necropsy show a pre dominance of the female sex. Anthracosis of the lung, which is observed rather frequently in Vienna, is often associated with tuberculosis of the lymph nodes and may involve other organs, but as Professor Sternberg emphasized during the general discussion, it should be borne in mind that the mere filling of the lymph nodes with coal dust (without tuberculosis) is sufficient to produce necroses. The invasion of the lung by the contents of a tuberculous node that has been quiescent for years may produce in an aged person severe inflammatory processes. The course of such processes is atypical, and the roentgenograms are deceiving. The course of events points to almost any other condition than to perforation of the mediastinal gland. In the discussion, all speakers agreed that the perforation in the child takes place differently than in aged persons. Dr Arnstein found in aged persons an average of 0.001 Gm as the titer for the intracutaneous test. It is evident that pure coal dust alone is rather harmless if it is not inspired in exceedingly large quantities. The danger is not great unless it is combined with tuberculous material in persons of advanced age.

## Coutard's Method of Treatment of Cancer of Larynx

In spite of excellent results that modern surgical methods have secured, treatment of cancer of the pharynx and the larynx with roentgen rays and radium has gained favor. The type of high dosage of roentgen rays recommended by Coutard has been tried out in Vienna by Professor Hajek in a series of cases. The results of these observations were reported at a recent session of the Vienna Laryngologic Society by Dozent Dr Wessely. In the past two years, 100 cases of operable and inoperable cancer have been treated by the Coutard method of irradiation. In a period of from four to six weeks a total of from 4,000 to 7,000 roentgens was administered in fractionated doses at as evenly divided intervals as possible, according to the degree of the reaction. The intensity of the reaction is measured by the appearance of a fibrinous inflammation of the mucosa. This fibrinous reaction on the mucosa is regarded by Coutard as an absolute proof of correct dosage, whereas other investigators regard it as the limit of toleration. The retrogression of the tumor begins in the second half of the series of irradiations and continues for some time after their completion. Many tumors disappeared so completely that the larynx regained its normal configuration. Occasionally remnants are left that may constitute 'tumor-containing' tissues or that may be "tumor free." In a few cases however, one observes rapid growth of the tumor beginning a considerable time after the irradiation was completed. The regeneration of the glands is usually less complete. The fibrinous coating on the mucosa, which is regarded by Coutard as the test of adequate dosage, is difficult to eliminate. Yet one gets the impression that the epithelium under the coating is well preserved. Resistance and duration of the fibrinous exudation on the mucosa vary with the individual. During the irradiation, and sometimes for several months afterward edema of the larynx may develop that will necessitate tracheotomy. Also necroses of the cartilages occur with aspiration pneumonia which has a bad prognosis. Operative interventions during the stage of the mucosal reaction and for some time afterward are dangerous because of the increased danger of infection and the weak resistance of the tissues. Diffuse tuberculosis, senility and cachexia

are contraindications to irradiation. Irradiation should not be continued if a "field" has been given the maximal dosage without effect, if true cachexia appears, if there is fever or if the mucosal reaction appears early and in an aggravated form. An operation after the irradiation is impossible, although the reverse is favorable, but recurrences after operation appear to react less promptly to irradiation. As the Coutard method has been in use but a short time, it is impossible to pronounce a final judgment on its permanent value. In any event it is excellent for inoperable cases, in which it gives at least temporary aid, and for patients who have an abnormal fear of operation, and in cases in which permanent mutilation is dreaded, for such mutilation is inevitable following a radical operation on cancer of the larynx. Operable cases, however, should be treated by operation, because modern operations show no higher mortality than irradiation, while the permanent results are possibly better.

#### Deaths

Prof. Dr. O. Weltmann, who was suffering from rheumatism and neuritis, yesterday took his own life. The decedent was only 48 years old. He was a prominent internist, whose addresses before the Gesellschaft der Aerzte always awakened great enthusiasm. His chief interest was in serology.

A second severe loss was the unexpected death of Hofrat Dr. Simon Kruger, medical director of the Städtliche Schwefelbader (sulphur baths under state supervision) in Baden, near Vienna. As general secretary of the German Balneological Society he had performed meritorious work in this field.

#### The International Red Cross Congress

The fifteenth International Red Cross Congress, which will be held in Tokyo, October 17-29, will be the first to be opened in the Orient. More than 100 representatives have already stated their intention to attend, including John Barton Payne from the United States. More than 300 members are expected to be present, including delegates from sixty-three nations, which are the member countries of the International Red Cross Society, delegates from fifty-eight Red Cross societies of the world, and representatives of twenty-eight international organs. The program is as follows:

Wednesday, October 17, meeting of the executive committee.

Thursday, October 18, assembly of the council of governors of the societies.

Friday, October 19, assembly of the governors of the societies in the morning, and assembly by the council of delegates in the afternoon.

Saturday, October 20, inaugural meeting.

Sunday, October 21, excursions.

Monday, October 22, plenary session in the morning, and meeting of the committees in the afternoon.

Tuesday and Wednesday, October 23 and 24, various committee meetings.

Thursday, October 25, assembly of the councils of governors of the societies.

Friday, October 26, plenary session of the conference.

Saturday and Sunday, October 27 and 28, excursions.

Monday, October 29, closing meeting.

The business agenda on the program of those meetings is as follows:

1 The duties of the Red Cross and other international organizations in international relief work.

2 The progress of ratification of the Geneva convention of 1929.

3 The bill of agreement for the fate of noncombatants or civilians in the enemy's territory or in land to be occupied.

4 Application of the Geneva convention and the prisoner code in a resort to arms without declaration of war.

5 Standardization of medical supplies.

6 Protection of civilians in time of war.

7 The duty of the Red Cross in the rapprochement of all nations.

8 The equipments of the Red Cross.

These are some of the important items to be discussed in the meetings.

#### Women in Medicine

Of more than 3,000 women doctors in Japan, only seven have received the highest title of "Igaku-Hakushi", that is, "Doctor of Medicine." Recently Prof. Kuni Toda of the Tokyo Women's Medical College received this title from the education office. Owing to various unavoidable difficulties, women have found it hard to continue their studies long enough to be honored with this title, which is given on presentation of a thesis. The present condition of the women doctors is rather disappointing, for they fall short of expectation. As for the men, there are 6,591 who have that high title among over 48,000 doctors. The Tokyo Women's Medical Society, which was organized in 1932, now has more than 1,200 members.

#### Abolition of Licensed Prostitution

After a fifty year campaign, licensed prostitution in Tokyo will before long be abolished. The brothels will be changed into restaurants or hotels or inns, and the prostitutes will become waitresses or barmaids. The system of unlicensed prostitution will, in truth, be approved. The notorious red light districts called "yoshiwara" in Tokyo, which for 400 years have been the center of public amusement, will be abolished. The prevention of venereal diseases is now under investigation by the police authorities. Out of fifty-seven prefectures, ten have already abolished licensed prostitution and six have ordered the prostitutes to change their occupations. According to reports from these prefectures, venereal disease seems to decrease year after year. If this decrease is really proved in Tokyo to be a fact, licensed prostitution will disappear all over the country in the course of time.

#### Medicinal Springs

About thirty years ago the medical department of Kyushu Imperial University established for the first time an institute at Beppu, the most noted watering place in Japan. Later, both the army and the navy established a sanatorium at the same town, chiefly for wounded soldiers. Various communities did likewise, but scientific research on the hot spring treatment has not yet definitely been done. Recently the Japan Medicinal Spring Society was organized with Dr. Haruo Hyashi, ex-dean of the medical department of the Tokyo Imperial University, president. The society will issue a monthly magazine and will hold a general meeting once a year.

In the Kagoshima prefecture, where hot springs abound, a medicinal spring research institute has been established under supervision of the local office.

#### The Academy Prize

The Academy Prize, which is the highest prize for scientific studies, for 1933 was given to Dr. Hiroshi Kon of the pathologic section of the medical department of the Hokkaido Imperial University for his studies on the silver reaction of protoplasm.

#### Physical Examinations of Conscripts

The war office has made public the results of a seven years statistical investigation of the health of conscripts. In 1927 there were 597,000 conscripts and in 1933 there were 565,000. The level of their health has shown a gradual fall of late, especially in those from the cities.

## Marriages

JOHN DENISON SPRING, Nashua, N H, to Miss Ethel Almira Benham of Clifton, N J, in New York, June 9

HERBERT W WORTHMAN to Miss Margaret McShane, both of Louisville, Neb, June 4

FRANCIS M TUSHLA to Miss Ruth J Shelley, both of Auburn, Neb, June 4

ELMER C McALEER to Miss Virginia B Milstead, both of Peru, Neb, recently

ARTHUR JAY PHILIP to Miss Ruth Ortman, both of Brooklyn, June 24

## Deaths

Otto Henry Schultze, Huntington, N Y College of Physicians and Surgeons in the City of New York medical department of Columbia College, 1889, member of the Medical Society of the State of New York formerly professor of medical jurisprudence, Cornell University Medical College, New York, coroner's physician for New York County, 1896-1897, borough of Manhattan, 1902-1915, medical assistant to the district attorney of New York County for many years, aged 67, died, July 4

Olga A Hoffman, North Madison, Ind, Indiana University School of Medicine, Indianapolis, 1931, member of the Indiana State Medical Association, on the staff of the Madison State Hospital, aged 33 died, June 15, in the Methodist Episcopal Hospital, Indianapolis, of meningitis, following a mastoid operation

James Lester Junk @ Connellsville Pa, University of Pennsylvania School of Medicine Philadelphia, 1907, past president of the Fayette County Medical Society, served during the World War, aged 54, on the staff of the Connellsville State Hospital where he died, May 20, of ruptured abdominal aortic aneurysm

John E Safford @ Stamford N Y, College of Physicians and Surgeons, Baltimore, 1895, formerly secretary of the Delaware County Medical Society at one time medical superintendent of the Stamford Hospital, aged 72 died May 12, in the Parshall Private Hospital, Oneonta, of heart disease

George W Gregg @ Canandaigua, N Y, Eclectic Medical Institute, Cincinnati, 1906, since 1931 city health officer aged 58, medical director and superintendent of the Canandaigua Health Home, where he was instantly killed June 2 when he was crushed between the elevator cage and the door

Llewellyn Roberts Johnson @ Los Gatos, Calif Cooper Medical College San Francisco 1903, served during the World War formerly superintendent of the Hewlett Emergency Hospital, Stockton, aged 52, died May 25, in St Luke's Hospital, San Francisco, of pulmonary tuberculosis

Sheridan Alfred Lockwood, San Diego Calif American Medical Missionary College Chicago, 1900, member of the California Medical Association aged 59 for many years on the staff of the Paradise Valley Sanitarium, National City, where he died, May 29, of pneumonia

Joseph Edward Gandy, Spokane, Wash, University of Michigan Medical School, Ann Arbor 1873 Civil War veteran, formerly member of the state legislature and member and president of the city council, aged 86, died June 2, of acute dilatation of the heart

Herbert William Casey, Brooklyn Long Island College Hospital, Brooklyn 1899 member of the Medical Society of the State of New York on the staffs of St Catherine's and St Mary's hospitals, aged 66, died, June 21, of subacute bacterial endocarditis

Edgar Allen Hawk, New Palestine Ind Central College of Physicians and Surgeons Indianapolis 1905 member of the Indiana State Medical Association president of the Hancock County Medical Society aged 55 died June 12 of gastric carcinoma

James Leonidus Fields, Jackson Tenn (licensed in Tennessee in 1911) member of the Tennessee State Medical Association aged 46 died May 26 in the United States Penitentiary Hospital Leavenworth Kan of carcinoma of the cecum

William Andrew Nield @ New Bedford Mass, Baltimore Medical College, 1902, formerly on the staffs of the Sassaquin Sanatorium and St Luke's Hospital, aged 59, died suddenly, June 12 in the Baker Memorial Hospital, Boston, of thrombosis

Harry Everett Nelson, New Orleans, Medical Department of the Tulane University of Louisiana, 1912, member of the Louisiana State Medical Society, on the staff of the Hotel Dieu Hospital, aged 48, died, May 16, of sarcoma

James H Ingram, Peiping, China, University of Pennsylvania School of Medicine Philadelphia, 1883, member of the Medical Society of New Jersey, for many years a medical missionary, aged 75, was shot and killed by bandits, June 15

Donald Platt Osborne, Kalamazoo, Mich, University of Michigan Medical School, Ann Arbor, 1902, member of the Michigan State Medical Society, aged 55, on the staff of the Borgess Hospital, where he died, April 28, of pneumonia

Ada Theodosia Hobby, Brooklyn, New York Medical College and Hospital for Women, New York, 1886, on the staffs of the Prospect Heights and Brooklyn Maternity hospitals, aged 75, died, June 13, of cerebral hemorrhage

Silas Warren Saxton @ Steubenville, Ohio, Jefferson Medical College of Philadelphia, 1903, served during the World War, aged 55, died May 16, in the Mercy Hospital, Pittsburgh, of uremia and chronic nephritis

Plomer Julius Gustin, Bedford, Iowa, University of Nebraska College of Medicine Omaha, 1927 member of the Iowa State Medical Society, aged 39, died, May 27, in Fort Meade S D, of a gunshot wound

Arthur Harry Meyers @ Mystic, Conn, Medico-Surgical College of Philadelphia, 1902, past president and secretary of the New London County Medical Society, aged 54, died, June 2, of heart disease

Samuel Goldstein @ New York, University of the City of New York Medical Department, 1892, aged 64, for many years on the staff of the Midtown Hospital, where he died, May 20, of uremia and nephritis

Samuel Lawrence Joyner, Ashland, La, Memphis (Tenn) Hospital Medical College 1903, member of the Louisiana State Medical Society, aged 58 died, May 28, in a sanatorium at Shreveport, of chronic nephritis

Kate Anna Mason Hogle, Mount Vernon, Iowa, Northwestern University Woman's Medical School, Chicago, 1885, member of the Iowa State Medical Society, aged 74, died, June 1, of cerebral hemorrhage

John Ramsey Dodenhoff, Springfield, S C, Medical College of the State of South Carolina, Charleston, 1912 aged 48 died, June 7, in the Columbia (S C) Hospital, of myocarditis and hypertension

Vernon Curry Morton @ Rantoul, Ill, College of Physicians and Surgeons, Keokuk, Iowa, 1897, on the staff of the Mercy Hospital, Champaign, aged 58, died suddenly, June 19, of angina pectoris

Edward Aloysius Treacy, Philadelphia, Jefferson Medical College of Philadelphia, 1913, aged 50, died, June 1, in the Frankford Hospital, of carcinoma of the cecum and peritonitis

Charles Wilbur Stroup, Ludlow, Ky, Cincinnati College of Medicine and Surgery, 1902 veteran of the Spanish-American and World wars, aged 54, died, May 26, of coronary embolism

Ulysses Grant Auer, Marion, Ind, University of Michigan Medical School, Ann Arbor, 1901, formerly on the staff of the Peoria (Ill) State Hospital, aged 65, hanged himself, June 1

George Edward Penn, Marvell, Ark Louisville (Ky) Medical College 1886 served during the World War aged 69 died May 31, in the U S Veterans' Hospital, Memphis, Tenn

William A Johnston, Roanoke, Va, College of Physicians and Surgeons Baltimore, 1881 aged 71, died, May 30, at his home in South Roanoke of carcinoma of the stomach

Thomas Blakeney Holmes @ Oakland, Calif Medical Department of the University of California, 1891 aged 68, died May 12 in the Peralta Hospital of myocarditis

Noah Danley, St. Joseph, Tenn Vanderbilt University School of Medicine Nashville 1901 member of the Tennessee State Medical Association aged 75 died May 6

Augustus Charles Schwartz, Toledo Ohio Howard University School of Medicine Washington D C 1890, aged 74 died June 8 of carcinoma of the esophagus

Martin Luther Finkbner, Parkerford, Pa., Medico-Chirurgical College of Philadelphia, 1906, aged 64, died, May 30, of cerebral hemorrhage with dementia

Winston Rives Haynes, Silver Spring, Md., Georgetown University School of Medicine, Washington, D C., 1923, aged 42, was found dead, June 8, of heart disease

Frederick Aloid Sedlacek, Omaha, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1897, aged 67, died, May 30

Herbert Carroll Ober, Newton, Mass., Boston University School of Medicine, 1916, aged 48, died, June 10, in the Winchester (Mass.) Hospital, of pneumonia

Robert C Talbot, Broken Bow, Neb., Miami Medical College, Cincinnati, 1870, formerly member of the school board and city council, aged 87, died, May 12

Romuald Tessier, Montreal, Que., Canada, School of Medicine and Surgery of Montreal, 1897, served during the World War, aged 59, died, May 10

David Reeves Stockton, Lancaster, Pa., Hahnemann Medical College and Hospital of Philadelphia, 1900, aged 66, died, May 4, of chronic endocarditis

Thomas Robert Plumer, Trivoli, Ill., Northwestern University Medical School, Chicago, 1930, aged 28, was killed June 24, in an airplane accident

Burton Dwight Stone, Baltimore, University of the City of New York Medical Department, 1882, aged 74, died, May 13, of carcinoma of the prostate

Malcolm M Crowder, Kensington, Ga., Southern Medical College, Atlanta, 1886, member of the Medical Association of Georgia, aged 74, died, May 7

Walter Ervin Seay, Jacksonville, Fla., Kentucky School of Medicine, Louisville, 1904, aged 61, died, May 11, of perforated ulcer of the stomach

Arthur C Bell, Oklahoma City, University of Louisville (Ky.) School of Medicine, 1891, aged 74, was found dead, May 13, of heart disease

Samuel Sheldon Robinson, Tulsa, Okla., Kansas City (Mo.) Hahnemann Medical College, 1903, aged 74, died, May 25, in a local hospital

James A Stothart, Savannah, Ga., University of Georgia Medical Department, Augusta, 1888, aged 80, died, May 13, of cerebral hemorrhage

Newton R Eastman, Mount Vernon, Ohio, Starling Medical College, Columbus, 1895, aged 62, died, June 16, of heart disease

Leroy S Barnes, Lynn Haven, Fla., Pulte Medical College, Cincinnati, 1881, Civil War veteran, aged 92, died, April 21

Peter G Pritchett, Timberlake, N C (licensed in North Carolina, year unknown), aged 87, died, April 10, of myocarditis

William Elias Whyte, Philadelphia, Howard University School of Medicine, Washington, D C., 1920, aged 47, died, June 6

Jacob Carson Tilson, Marshall, N C., Tennessee Medical College, Knoxville, 1892, aged 74, died, June 15, of heart disease

Edgar W Rine, Winchester, Ind., Starling Medical College, Columbus, 1885, aged 75, died, June 5, of heart disease

Fannie Emanuel, Chicago, Chicago Hospital College of Medicine, 1915, aged 61, died, March 31, of diabetes mellitus

Benjamin Lee Jean, Deltrose, Tenn., Vanderbilt University School of Medicine, Nashville, 1896, aged 62, died, June 3

Harry Homer Goyer, North Little Rock, Ark., Memphis (Tenn.) Hospital Medical College, 1909, aged 48, died, May 12

Joseph Warren Sanborn, Waldoboro, Maine, Medical School of Maine, Portland, 1894, aged 65, died, March 5

V J Brown Sr., Buckhead, Ga., Tennessee Medical College, Knoxville, 1905, aged 56, died, May 30

John C Buttemiller, Cincinnati, Medical College of Ohio, Cincinnati, 1877, aged 80, died, May 18

W Mark Patterson, Seattle Eclectic Medical Institute, Cincinnati, 1886, aged 81, died, May 29

Kince Manly Counce, Martin, Tenn. (licensed in Tennessee in 1905), aged 58, died, April 22

James M Adkins, Liberty, Mo., Kansas City Medical College, 1880, aged 76, died, June 2

Joseph A Farmer, Milstead, Ga., Atlanta Medical College, 1891, aged 76, died, May 15

## Bureau of Investigation

### MISBRANDED "PATENT MEDICINES"

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

[EDITORIAL NOTE The abstracts that follow are given in the briefest possible form (1) the name of the product, (2) the name of the manufacturer, shipper or consigner, (3) the composition, (4) the type of nostrum, (5) the reason for the charge of misbranding and (6) the date of issuance of the Notice of Judgment—which may be considerably later than the date of the seizure of the product]

**Var ne sis for Rheumatism**—Var ne sis Co., Lynn, Mass. Composition Essentially sodium salicylate extracts of plant drugs including licorice with alcohol and water. Fraudulent therapeutic claims—[N J 18052 18053 18057 August 1931]

**Marshall's Cubeb Cigarettes**—James B Horner Inc., New York N Y. Composition Ground cubeb. For catarrh, hay fever, asthma, etc. Fraudulent therapeutic claims—[N J 18054 August 1931]

**Hydras**—John Wyeth & Bro., Philadelphia, Pa. Composition Essentially extracts of plant drugs including hydrastis with alcohol, glycerin, sugar and water. For female disorders. Fraudulent therapeutic claims—[N J 18056 August 1931]

**Pike's Centennial Salt Rheum Salve**—J J Pike & Co., Chelsea, Mass. Composition Essentially petrolatum with a small amount of sassafras oil. For salt rheum, corns, diphtheria, etc. Fraudulent therapeutic claims—[N J 18063 August 1931]

**Potasafras**—Columbia Chemical Corp., Columbus, Ohio. Composition Essentially potassium iodide compounds of sodium and magnesium sulphates, a trace of phosphate, benzoic acid, extracts of plant drugs including licorice with sugar, alcohol and water. For blood disorders, etc. Fraudulent therapeutic claims—[N J 18065 August 1931]

**Herst's Intestinal Cloanser**—Health Food Laboratories, Kansas City, Mo. Composition Essentially ground senna, alfalfa, licorice, chamomile and anise. Fraudulent therapeutic claims—[N J 18072 August 1931]

**Antiseptic Konoids**—Konoid Co., New Orleans, La. Composition Essentially tannin, salicylic acid and boracic acid in cocoa butter. For female troubles. Fraudulent therapeutic claims—[N J 18073 August 1931]

**Gold Thread Syrup Compound A**—Gold Thread Syrup Co. Inc., South Berwick, Me. Composition Essentially creosote extracts of plant drugs with sugar, water and mint flavoring. For coughs, bronchitis, indigestion, etc. Fraudulent therapeutic claims—[N J 18076 August 1931]

**Burton's Relief**—Carolina Medicine Co., Littleton, N C. Composition Small quantities of extracts of plant drugs with colchicin and water and red coloring. For rheumatism, blood disorders, etc. Fraudulent therapeutic claims—[N J 18077 August 1931]

**Neo Cullol**—Arlington Chemical Co., Yonkers, N Y. Composition A Bacillus Acidophilus preparation. For auto-intoxication. Misbranded and adulterated. Fraudulent therapeutic claims—[N J 18079 August 1931]

**Hakka Cream Compound**—Hakka Chemical Co., Boston, Mass. Composition Essentially petrolatum, boric acid, menthol, camphor and traces of carbolic acid and hexylresorcinol. For catarrh, hay fever, etc. Fraudulent therapeutic claims—[N J 18080 August 1931]

**Thall's Rheumatic Tablets**—Thall's Home Remedy Laboratory, Manchester, N H. Composition Acetphenetidin (acetanilid) 2 grains per tablet, quinine (15 grains per tablet), small proportions of extracts of plant drugs and caffeine. Fraudulent therapeutic claims—[N J 20157 June 1933]

**Tal O Rub**—McHesson Hall, Van Groder Co., Cleveland. Composition Essentially extract of red pepper with eucalyptol, menthol and camphor in a petroleum ointment base. For croup, lumbago, rheumatism, etc. Fraudulent therapeutic claims—[N J 20152 June 1933]

**Granger Liver Regulator**—Granger Medicine Co. (Estorge Drug Co.), New Thieria, La. Composition Essentially senna and a small amount of other plant material. For dyspepsia, kidney and liver disorders, etc. Fraudulent therapeutic claims—[N J 20155 June 1933]

**Thall's Antiseptic Roots**—Thall's Home Remedy Laboratory, Manchester, N H. Composition Coarsely ground bitter dock and cranesbill. For leucorrhoea and gleet, ulcers and sores. Misbranded because of fraudulent therapeutic claims. Adulterated because of low strength drugs—[N J 20157 June 1933]

**Thall's Cough Syrup**—Thall's Home Remedy Laboratory, Manchester, N H. Composition Plant drug extracts, a benzoic acid compound, tar, a small quantity of creosote with sugar, alcohol (5.24 per cent) and water, flavored with caramel. Fraudulent therapeutic claims—[N J 20157 June 1933]

**Thall's Female Tonic**—Thall's Home Remedy Laboratory, Manchester, N H. Composition Essentially plant drug extracts, sodium benzoate, sugar, alcohol (49 per cent) and water. For profuse menstruation, menorrhagia, etc. Fraudulent therapeutic claims—[N J 20157 June 1933]

**Thall's Female Tablets**—Thall's Home Remedy Laboratory Manchester N H Composition Extracts of plant drugs and strychnine (0.023 grain per tablet) For menstrual irregularities Fraudulent therapeutic claims—[N J 20157 June 1933]

**Indian New Discovery**—Justice Drug Co Greensboro N C Composition Essentially chloroform, ether, ammoniac volatile oils including camphor, turpentine and sassafras with alcohol and water For rheumatism etc Fraudulent therapeutic claims—[N J 20151 June 1933]

**Thall's Kidney Tonic**—Thall's Home Remedy Laboratory Manchester N H Composition Essentially plant drug extracts including valerian a trace of alkaloids and small quantities of volatile oils including pepper mint with sugar alcohol (4.46 per cent) and water Fraudulent therapeutic claims—[N J 20157 June 1933]

**Thall's Nerve Syrup**—Thall's Home Remedy Laboratory Manchester N H Composition Essentially plant drug extracts including valerian and licorice a trace of alkaloids with sugar alcohol (4.28 per cent) and water caramel flavored For epilepsy hysteria convulsions etc Fraudulent therapeutic claims—[N J 20157 June 1933]

**Thall's Lung Tonic**—Thall's Home Remedy Laboratory, Manchester N H—Composition Essentially plant drug extracts including wild cherry and licorice with sodium benzoate sugar alcohol (2.0 per cent by volume) and water Fraudulent therapeutic claims—[N J 20157 June 1933]

**Thall's La Grippe Capsules**—Thall's Home Remedy Laboratory Manchester, N H Composition Quinine sulphate (0.7 grain per capsule) ammonium chloride camphor and extracts of plant drugs Fraudulent therapeutic claims—[N J 20157 June 1933]

**Creme Crede**—Scientific Products Laboratories Lincoln Neb Composition Essentially boric acid, tragacanth glycerin a small amount of lactic acid traces of phenolic compound and a volatile oil and water For female disorders and feminine hygiene Fraudulent therapeutic claims—[N J 20158 June 1933]

**Hutchison's Big Head Liniment**—Hutchison Medicine Co, Texarkana Tex Composition Essentially turpentine oil petroleum oil and a trace of mercuric chloride Fraudulent therapeutic claims—[N J 20159 June 1933]

**Hutchison's Maple Oil**—Hutchison Medicine Co Texarkana Tex Composition Essentially oleoresin of red pepper with small amounts of camphor peppermint oil a salicylate and tannin alcohol a trace of chloroform and water Fraudulent therapeutic claims—[N J 20159 June 1933]

**Biz**—Henderson & Skipworth San Francisco Composition Essentially carbolic acid camphor and alcohol (6.3 per cent) For skin disorders Fraudulent therapeutic claims—[N J 20160 June 1933]

**Sinapole Ointment**—The Sinapole Co Los Angeles Composition Petrolatum with volatile oils including mustard oil For pleurisy rheumatism pneumonia, etc Fraudulent therapeutic claims—[N J 20164 June 1933]

**Scarlet Red Salve**—Heilkraft Medical Co Boston Composition Petrolatum boric acid a zinc compound eucalyptus oil and a red dye (Scarlet R) For varicose ulcers eczema etc Fraudulent therapeutic claims—[N J 20165 June 1933]

**Armstrong's Granular Effervescent Lithia Compound**—Armstrong Chemical Co Boston Adulterated because below professed standard in strength and purity Misbranded because claimed to contain caffeine citrate which it did not—[N J 20166 June 1933]

**Arlum**—Fuller Morrison Co Chicago Composition in each tablet 2.6 milligram of radium and 0.02 milligram of strychnine Misbranded because statement Radium in Tablets was false and misleading since they also contain strychnine also because of false and fraudulent therapeutic claims—[N J 20168 June 1933]

**Brander's No 7**—Haley M O Co Inc Geneva N Y Composition Essentially small quantities of soap phenols glycerin and water (99%) For feminine hygiene female disorders etc Not antiseptic when diluted with equal volume of water Fraudulent therapeutic claims—[N J 20171 June 1933]

### PYRETHRUM SENSITIZATION COMPLICATING HAY FEVER

*To the Editor*—Commercial "Pyrethrum" is widely used for its toxic effects in various types of insecticides. The flowers of certain species of pyrethrum plants, of the genus *Chrysanthemum*, are used for the preparation of the substance, and closed flowers, which contain much pollen, apparently are the most satisfactory. For some years it has been known that dermatitis and allergic manifestations in the respiratory tract may occur as the result of exposure to this toxic material.

Ramirez (Pyrethrum, *J Allergy* 1 149 [Jan] 1930) reported two cases, one of sensitiveness to grass and the other to ragweed pollen, in which sensitization rhinitis occurred after the regular pollen seasons had terminated. These patients were found to be sensitive to pyrethrum and had been exposed to insecticides containing it.

Feinberg (Pyrethrum Sensitization, *THE JOURNAL*, May 12, 1934, p 1557) called attention to the frequency of sensitization to pyrethrum in the ragweed pollen sensitive group. He believes that sensitivity to it occurs only in ragweed pollen sensitive patients because both plants in question belong to the order of *Carduales*. This author feels that such sensitivity is the cause of hitherto unexplained attacks of hay fever or asthma during months exclusive of the usual hay fever season.

Pyrethrum sensitization offers still another problem in hay fever other than postseasonal allergic symptoms. It is the matter of exposure to insecticides containing pyrethrum as an explanation of apparently unsuccessful treatment with pollen extracts one season, whereas in previous years such treatment had been successful. Such cases have been seen. One was that of an individual sensitive to ragweed pollen, and the other that of a patient sensitive to Russian thistle in a part of the United States where ragweed is of minor importance.

A young woman sensitive to giant ragweed had received very satisfactory relief in the preceding two years by treatment with injections of pollen extract. In the summer in question, after at least half the ragweed season had been passed asymptotically the patient began to suffer from the symptoms of sensitization rhinitis. A widely used "fly powder" was suspected as the result of questioning. Skin tests were positive for pyrethrum, and relief was obtained by discontinuing the use of the insecticide.

A young man sensitive to Russian thistle had been quite satisfactorily relieved from hay fever by pollen extract treatment in previous summers. Though relief had not been complete, results were satisfactory as contrasted to the severe symptoms he had had before treatment. One summer he began to clerk in a grocery store during the Russian thistle season and noted the symptoms of hay fever almost every evening. He suspected "Flit," which was liberally sprayed about the store at closing hours. A positive skin test to pyrethrum was obtained. Elimination of insecticides was followed by relief of hay fever symptoms.

It may be concluded that

- 1 Pyrethrum, commonly used in insecticides, may cause hay fever and asthma.
- 2 A patient may have coexistent sensitivity to this substance and to pollens of grasses and weeds.
- 3 Exposure of such an individual to an insecticide containing pyrethrum may explain the apparent failure of desensitization for hay fever in a case theretofore successfully treated.

## PSORIASIS AND CLIMATE

To the Editor—I was much interested in your answer to Dr Albert M Crance of Geneva, N Y, in *Queries and Minor Notes* (THE JOURNAL, June 2, p 1873), concerning the frequency of psoriasis in tropical countries. Although I agree that the disease in question seems to be less frequent in the tropics, it is by no means a rarity. Kayser, quoted by Ormsby (*Diseases of the Skin*, New York, Lea & Febiger, 1921, p 261), states "In the tropics, the subjects of psoriasis are few, and the symptoms of the disease, when they develop at all, are rudimentary, the typical eruption being scarcely ever produced." Kayser writes of the disease in the Dutch East Indies and his contentions may be true so far as they concern the colored races, in which psoriasis is very rare. In the whites residing in the tropics the disease is frequent and offers the same

## Disease in Tropical Countries

	Personal Statistics	Statistics of American Dermatological Association *
Psoriasis	1 121 per cent	2 650 per cent
Lupus erythematosus	0 922 per cent	0 356 per cent
Vitiligo	1 022 per cent	0 250 per cent
Lupus vulgaris	0 071 per cent	0 234 per cent

\* J Cutan Dis April 1914 p 312

characteristics observed elsewhere. Another cutaneous disease that is thought by many to be rare in the tropics is lupus erythematosus. Contrary to this statement, lupus erythematosus seems to be more frequent in Cuba than in the United States. Vitiligo, which is supposed to be very common in tropical countries, is actually less frequent than psoriasis in Cuba. Tuberculosis of the skin, lupus vulgaris in particular, is very rare. The following statistics are self explanatory. My own observations are based on a total of 7,042 cases of skin diseases exclusive of syphilis.

V PARDO CASTELLO, M D, Havana, Cuba

## PRISON PHYSICIANS

To the Editor—I have read with great interest the communication in THE JOURNAL May 19, by Dr James L McCartney, director of the Classification Clinic of Elmira Reformatory and secretary of the Medical Section, American Prison Association.

My knowledge of prisoners and prisons has been gleaned only from one prison during twelve years of medical service as resident physician State Institutions Howard R I, over a decade ago. I have had the impression that the medical service of the prisons in the United States was excellent and that under such a service the condition of the prisons and the state of the prisoners' health was benefited and conserved. From what I have read of the methods of modern penology, there has been a great uplift all the way along, both in the prisoners' morale and in his physical environments. Those physicians whom I had met at some of the prison conventions, far from being the "derelicts of medicine," appeared to be men well versed in modern methods of treatment, had pride in their work, and apparently had the confidence and esteem of the prison warden. In fact in the days to which I refer the outstanding trio or triple alliance, 'was the warden, the prison physician and the chaplain. The combined efforts of these men usually was of great importance to the prison morale, for discipline was tempered with the kindness and mercy that are the feature of medical and religious training.

There are several factors to be taken into consideration in the employment of the medical service of prisons and other

penal or reformatory institutions. In the first place, the annual appropriation in all such institutions is woefully inadequate and is usually gotten through the legislature by a good deal of jockeying and paring down in all departments. The less assertive and usually subordinate departments, as the medical, are apt to remain stationary. Increases in salary are small and promotion is slow, and the incumbents of these positions remain as they were engaged, e g, "prison physician." If there is difficulty in obtaining appropriations for medical service and supplies, this service tends to remain stationary, if not retrogressive.

It would seem as if the advancement of the medical service in prisons might well be urged by THE JOURNAL, and that this important social service be not left entirely to the care of the "derelicts" and "cast offs" of the medical profession.

In all prisons there is ample opportunity for the physician to do good work, for the building up both of the morale and of the physical condition of the prisoners, for in many instances when they fall sick and are removed for a time to the hospital ward, away from the irritating discipline of the daily routine, the more kindly treatment and atmosphere of the medical environment has been in many instances the first step toward the reformation and the redemption of the prisoner, and that really should be the ultimate aim of all those engaged in this form of service. Certainly the lamentations of Dr McCartney would be a timely topic for discussion before the Medical Section of the American Prison Association at its next meeting.

HENRY A JONES, M D, Auburn, R. I.

## Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted on request.

## VOMITING IN INFANCY

To the Editor—For four months a girl aged 20 months has vomited nearly every night after one or two hours of sleep. She awakens crying. If left lying quiet she will vomit and also if she is taken up. Her nutrition and growth are fair. The only illnesses have been infections of the upper respiratory tract sometimes accompanied by otitis media. A slight rise in temperature is usually accompanied by a mild convulsion. The vomiting occurs nightly regardless of whether she is sick or well. Her parents are very nervous. Except for probable laxness in habit training she has been well cared for. What are possible causes for such a condition? How may a diagnosis be arrived at? Please give suggestions for treatment. Kindly omit name. M D Michigan

ANSWER—It does not seem possible to answer this question categorically. It is obvious that vomiting as it occurs in a baby aged 20 months may be due to a variety of causes, and in order to arrive at a definite conclusion a painstaking examination will be required in order to exclude a number of possibilities. It seems, however, that the significant points, as stated in the query, are the previous history of otitis media, and fever accompanied by convulsions associated with vomiting. Vomiting may be due to pyloric stenosis, though this usually occurs in young infancy and does not come up for consideration in this case. Infants suffering from gastro intestinal diseases or peritonitis usually have abdominal pains as well as vomiting and a variety of other symptoms that have not been noted in the case of this infant. Vomiting may occur also during an attack of catarrhal jaundice or may result from the presence of foreign bodies in the gastro-intestinal tract. It also should be noted that vomiting may be caused by various vegetable and mineral poisons, such as acids, alkalis, poisonous gases and a variety of drugs, especially emetics and expectorants, and it may also be due to the ingestion of spoiled food. The history of the patient would indicate the presence or absence of any of these factors. Vomiting may occur also as the result of nephritis, chronic uremia, cystopyelitis and diabetes. Repeated examination of the urine would clear up the diagnosis, if any of these factors should be present.

One would also think of cyclic vomiting which, however, occurs more frequently during the day and is usually associated

with persistent moderate fever and great prostration. In these cases the urine nearly always shows the presence of acetone and diacetic acid, and the breath has a sweetish aromatic odor.

Vomiting may occur also in chronic nasal and faucial infections, adenoid vegetations, hypertrophy of the tonsils and acute sinusitis, though aside from the ethmoid sinuses the others are not developed at this early age. In acute otitis media in young life, vomiting, convulsions and delirium with a rise in temperature are frequently observed. Vomiting may be associated with epileptic seizures as well as with the rarely occurring attacks of migraine at this age. In epilepsy the convulsive seizures are characteristic, in migraine there would be evidence of pain and great restlessness.

One should bear in mind the possibility of an intracranial process in this case. The history of recently suppurating ears is significant.

One would think of the possibility of a brain abscess or localized septic meningitis or thrombophlebitis, more remotely of a brain tumor, hemorrhage of the brain and encephalitis or cerebral sclerosis. In a thrombophlebitis the temperature is apt to be remittent, whereas in a septic meningitis the temperature is continuously high, and in brain abscess the temperature may be only slightly elevated with irregular remissions below normal. The vomiting in these conditions may be projectile but is more frequently regurgitant. The most common symptoms of brain abscess are vomiting, headache, choked disk, constipation, subnormal temperature and slow pulse. Not all of these symptoms are present in any one case, nor are they all present as a rule at the onset of the disease. Next to headache, vomiting is the most frequent symptom, though in an encysted abscess the vomiting may be entirely absent. The important point about vomiting, if it is present, is that it may be projectile sometimes regurgitant, and it occurs without nausea. Choked disk, if present, signifies increased intracranial pressure and constitutes an important link in the diagnosis of abscess or tumor.

It is true that vomiting may occur in the course of acute otitis media, but, if it persists, an intracranial complication should be suspected.

In short, the solution of the problem at hand depends on the process of reasoning by exclusion. A carefully elicited history and examination of the blood and especially the urine, and a complete neurologic examination with the investigation of the special sense organs, should aid materially in differentiating an organic lesion from a functional disorder.

#### ERYTHEMA NODOSUM

To the Editor—A farmer's son always healthy, developed at the age of 2 a circumscribed red swelling on the dorsal surface of the right forearm. This swelling was hard and somewhat tender and about 38 mm in diameter. The boy was then taken to a physician who thought that, with heat the swelling would suppurate and would then have to be opened. Accordingly heat was applied but this did not result in any change in the lesion. All treatment was discontinued and the lesion disappeared spontaneously in about three weeks. A larger lesion of the same type and appearance appeared at the same site two years later at about the same period of the year as far as I could learn. This time an ice pack was applied with the same negative results. The lesion disappeared about two weeks after the discontinuance of treatment three and a half weeks after its inception. When seen by me on about the middle of November when the patient was 9 he had been free from the ailment for the last six years. Physical examination revealed absolutely nothing of significance as far as the various systems were concerned. The family history was also entirely negative. There was no elevation of temperature. On the right forearm extending from the midline of the dorsal side to about the midline of the medial border and from about two fingerbreadths above the wrist to about the same distance caudad from the elbow appeared an oval area of dark red induration and elevation. The swelling rising to about 20 mm above the rest of the forearm was sharply delimited but the redness faded gradually into the natural color of the rest of the body. The lesion was firmly attached to the muscles underneath and was somewhat tender to the touch. The patient stated however that he could sleep well on that side. The skin over the lesion did not seem particularly hot. The father was concerned principally because of the danger of the lesion involving a joint at some future attack. He stated that the lesion never grew in size once established the whole area was involved at the outset. The child felt perfectly well and played with other children all day. Laboratory examination revealed: Urinalysis: no albumin, sugar nor casts; specific gravity 1.022; reaction alkaline. Blood: white count 8,200; polymorphonuclears 72 per cent, large lymphocytes 9 per cent, small lymphocytes 11 per cent, large mononuclears 7 per cent, mast cells 0, eosinophils 3 per cent, blood pressure 108 systolic 44 diastolic. A biopsy was suggested but refused. The patient was urged to come back but did not. He can be located however if necessary. What is your suggestion as to the diagnosis and treatment of this case? Kindly omit name and town.

M D Wisconsin

ANSWER—It is always hazardous to make a diagnosis from a written description but the description of the lesions together with the location and the fact that the lesions persisted for

about three weeks would strongly suggest the diagnosis of erythema nodosum. This condition is not uncommon and in the United States is regarded as due to influences similar to those which cause rheumatic disturbances, although the disease is not a part of rheumatic fever. The fact that there were 72 per cent of the polymorphonuclear leukocytes in the blood, a high figure for a boy of 9, would tend to confirm the diagnosis of an infectious process. The treatment of erythema nodosum is symptomatic and salicylates have commonly been used with relief of symptoms. Foci of infection should be searched for and eradicated if found.

The differential diagnosis would involve such other conditions as urticaria and tularemia, but urticaria is never characterized by a persistent lesion. The wheals in this condition come and go, and while the whole condition may last over long periods of time the individual lesions rarely persist more than one or two days and are characterized by white centers and by itching. The 3 per cent eosinophilia must be considered normal and not indicative of urticaria.

In tularemia the history of contact with rabbits and the presence of a local ulcer should make the diagnosis clear. Furthermore, tularemia does not recur.

#### DIFFERENTIAL DIAGNOSIS OF SKIN LESION

To the Editor—I have under my care a woman aged 28 who has two fixed eruptions on her body, one being on the left side of her neck and about 30 mm in diameter the other over the right scapula being about 38 mm in diameter. These areas appeared two years ago three days after parturition. The labor and puerperium were otherwise normal. These areas are flat, are purplish brown, become sore near each menstrual period and then become scaly on top. The scales come off and there is no more sensation until the next menstrual period. Occasionally (every three or four months) these areas become studded with blebs ranging in size from a pinhead to a split pea. These last for a number of days and spontaneously disappear without rupturing. When these blebs are in evidence the areas itch severely. At the time these areas appeared the patient was taking fluidextract of ergot and no other drug. At the time of their appearance they were very small and are continuously enlarging. The Wassermann and Kahn blood reactions are negative as is the past history. Could you from this description supply me with a diagnosis and an adequate treatment? Kindly omit name.

M D Kentucky

ANSWER—This case might be (1) a fixed drug eruption, (2) recurrent herpes simplex, (3) dermatitis factitia—self-inflicted injury, or (4) dermatitis dysmenorrhoeica symmetrica of Matzenauer and Pollard.

1 Fixed eruptions due to arsphenamine, neoarsphenamine, antipyrine, phenolphthalein, amidopyrine and alurate (allyl-isopropyl-barbituric acid) a constituent of allonal (allyl-isopropyl-barbituric acid with amidopyrine), are well known and not rare. The case under discussion seems to fit the description of these fairly well, the lesion becoming inflamed and sometimes vesicular or bullous after the ingestion of the drug. This inflammation then subsides and leaves pigmentation of the whole area involved. At the next use of the drug the same process occurs, usually involving a greater area and often one or several new areas. It is stated that no drug except fluidextract of ergot was being taken. Patients often forget to mention to the doctor drugs considered household remedies. They have been known to deny repeatedly the use of phenolphthalein, for instance only to confess finally that they did take it but considered it unimportant. This matter must be thoroughly investigated.

2 Herpes simplex sometimes recurs in the same place at frequent intervals. This is particularly apt to occur at the menstrual periods. It is usually confined to one area and seldom leaves much pigmentation. It is nearly always vesicular, while vesicles occurred in only two of the attacks. Local roentgen treatment with small doses, one-fourth erythema dose once a week for not more than eight doses, and the administration of calcium in large doses, 3 or 4 Gm of calcium lactate three times a day after eating are the best methods of treatment.

3 Self-inflicted injury to the skin occurs in hysterical patients for the purpose of attracting interest or sympathy or to obtain compensation. The lesions are often of a peculiar shape angular or with a streak below the main patch where the liquid cauterant used usually phenol, has run down. Often one or several areas of hysterical anesthesia may be found. Proof of the guilt of the patient may be obtained by sealing the involved area with a dressing that prevents access to the skin. It must really prevent access to the skin, for these patients are shy and often outwit the doctor. If the lesions are self-inflicted they quickly heal by this method. Further proof may be obtained by suggesting that at a certain time a new lesion will appear in some particular area.

4 The dermatitis of Matzenauer and Pollard is characterized by a succession of (a) burning or tingling sensations, (b) erythema, (c) edema, (d) vesiculation, (e) exudation, (f) hemorrhage, (g) crust formation and (h) pigmentation, some cases going on to necrosis. It was held by many critics to be dermatitis factitia, for the patients are neurotic and the lesions on the extremities are elongated. The authors recognized that this would be claimed and made every effort to prove that the lesions were not self inflicted. The case under discussion occurred first soon after parturition and no mention is made of dysmenorrhea, which is an important feature of the Matzenauer and Pollard disease. Nothing is said of follicular exudate or hemorrhage, which are also important. The fact that the lesions are not exactly symmetrical may be disregarded, for in Wise and Parkhurst's case (So-called Dermatitis Dysmenorrheica, *Arch Dermat & Syph* 2 725 [Dec] 1920) they were unilateral. Treatment should be directed to relief of the dysmenorrhea. This may not succeed, however, in preventing the dermatitis.

#### INCUBATION PERIOD OF RABIES IN DOGS

To the Editor—I should like to know for how long a period it is advisable to keep a dog under observation for the development of rabies after it has bitten a person. I should also like to know in case a dog has been inoculated against rabies whether the examination of its brain would reveal actual changes and if so for how long a period after inoculation these would probably last. In other words is a positive report on a dog that has been inoculated to be interpreted always as proof that the dog has rabies? Kindly omit my name.

M D North Carolina

ANSWER—The average period of incubation of rabies in the dog is said to be from twenty-one to forty days. The period of incubation is dependent, in the main, on the place of the wound of entrance, its relation to nerves, and of course the amount and virulence of the virus introduced. It may be recalled that in dogs rabies may be diagnosed from the symptoms, from finding Negri bodies and certain characteristic anatomic changes in the central nervous system, and by inoculation of animals. The symptoms are often highly suggestive and occasionally even highly characteristic, but the final diagnosis in most cases will rest on the examination of the nervous system and, in special cases, on animal inoculation. In the present state of knowledge, the finding of typical Negri bodies in a dog must be regarded as proof of the presence in the dog of rabies even if the dog in question has been inoculated with killed rabies vaccine.

#### RINGWORM INFECTION OF HANDS AND FEET

To the Editor—A man aged 33, has an intractable tinea infection of the toes feet right hand and scalp. The primary focus was in the fourth interdigital spaces of the feet and was incurred about 1920 while the patient was residing in southern Florida. Iodine dusting powders and Whitfield's ointment were used and apparently kept the infection in check. However the original infection was never completely eradicated. In 1927 a body rash caused the patient to seek the advice of an eminent dermatologist in Cincinnati. It responded well to the treatment but the primary focus between the toes was not eliminated. In 1931 a vesicular eruption which itched severely was noted on the fingers of the right hand. A roentgen therapist gave a course of roentgen treatments which caused an apparent cure for six months. Economic circumstances prevented a continuance of treatment. In 1933 severe itching of the scalp was noted. At present the infection involves the plantar surfaces of the feet the toes the right palm and fingers and the scalp. Epidermophyton was isolated from the toes and the vesicles on the hand. The eruption at present is dry scaling and fissured. The palm of the right hand is red. Kindly outline the management of this case particularly in relation to the hand and the scalp. X rays are out of consideration because of the remote location. Please omit name.

M D Indiana

ANSWER—The condition as described is in all probability an eczematoid ringworm infection of the hands and feet. As ringworm involvement of the scalp is exceedingly rare in adults, it is improbable that the disorder in this location has any connection with the eruption on the extremities and it is impossible to suggest treatment for this condition without having an idea as to its probable nature.

With regard to the infection of the hands and feet, this disorder in these locations is in many instances notably rebellious to all treatment and it is necessary to try one or another of the parasitocidal preparations which vary greatly in the results produced in different individuals. In the chronic stage of the disorder such as is now presented the preparation of phenylmercuric nitrate as described by Levin in *THE JOURNAL*, Dec 26 1933 has been successfully used in a number of cases. Preparations containing sulphur salicylic acid or tar and dyes such as Castellani's carbolfuchsin paint are useful. Ultraviolet radiation is also of value in some cases of this type and may be given a trial particularly if roentgen treatment is not available.

#### SYPHILIS IN PREGNANCY

To the Editor—Mr K aged 30 husband of Mrs K aged 37 presented himself to me three and one half years ago as a blood donor for Mrs K. Then Miss D and I discovered that he had a 4 plus Wassermann reaction. I immediately commenced active antisyphilitic treatment on Mr K consisting of nearsphenamine four courses bismuth compounds four courses mercury compounds five courses and bismuth arspenamine sulphinate one course (three years). Miss D gave negative reactions in 1931 1932 and 1933 though she was exposed to infection during this time. Miss D has not received any antisyphilitic treatment. The Wassermann reports on Mr K in 1933 were negative twice (February and July). In December 1933 Mr K and Miss D were married and one month later Mrs K became pregnant. At present Mr K is receiving 0.6 Gm of nearsphenamine monthly (since negative reports) and Mrs K has a negative Wassermann report (six weeks pregnant). What routine ought I to follow in these cases bearing in mind that Mr K has never presented any syphilitic symptoms pupillary changes skin signs or neurologic symptoms. Mrs K has been well and during her pregnancy has had only slight morning sickness. Would you subject both Mr and Mrs K to active antisyphilitic treatment taking necessary precautions for a normal child? The child is due October 1. Would you repeat monthly Wassermann tests? Would you consider them as noninfectious? What instructions would you give these patients?

M D New Jersey

ANSWER—The probability is that this couple will have a normal healthy child whether treatment is administered during pregnancy or not. It would be safer, however, to give Mrs K at least a short course of treatment at this time as an added precaution. A monthly Wassermann test does no harm. It is difficult to answer the question of noninfectiousness without knowing more of the facts, that is, dosage of drugs used, number of treatments in each course, physical observations, spinal fluid, and so on. No special instructions need be given at this time. A little more instruction in birth control prior to marriage would have been more pertinent in view of the husband's known syphilitic infection. McKelvey and Turner's article entitled "Syphilis and Pregnancy. An Analysis of the Outcome of Pregnancy in Relation to Treatment in 943 Cases" (*THE JOURNAL*, February 17, p 503) should be consulted.

#### SPREAD OF SCARLET FEVER

To the Editor—1 What are the modern ideas concerning contagion in scarlet fever? Is it spread solely by nasal and throat secretions? 2 In view of the fact that the undisputed (?) etiologic factor is the non spore forming *Streptococcus scarlatinae* cultures of which can be obtained only in certain mediums under certain conditions of pH and temperature is it conceivable that rooms books clothing and the like can convey infection to other individuals? 3 Apart from the legal aspects is quarantine recommended for scarlet fever or infectious precautions as in pneumonia? In either case for how many days? Does injection of potent antiscarlatinal serum shorten this period? Please omit name and address.

M D China

ANSWER—1 Scarlet fever is usually spread by nose and throat secretions of persons who have scarlet fever are convalescent from the disease, or are immune carriers. It may also be spread by discharges from otitis media, mastoiditis or other suppurative conditions associated with scarlet fever. The spread of scarlet fever by milk is sometimes responsible for epidemics.

2 It has been shown that the air in a room occupied by a scarlet fever patient may be contaminated. Articles in the room may likewise be contaminated. The streptococci do not live long on such objects as books and clothing. Most cases of scarlet fever attributed to using books or clothing long after a case of scarlet fever occurred in the family have probably been due to recent contact with an unrecognized carrier of scarlet fever streptococci.

3 Quarantine is recommended for scarlet fever. The quarantine should be maintained until cultures on blood agar plates are negative for scarlet fever streptococci or until susceptible persons with whom the patient may come in contact are immunized. If a potent scarlet fever antitoxin is injected early in the disease it usually shortens the period of infectivity.

#### OUTFIT TO DETERMINE ICTERUS INDEX

To the Editor—Please tell me what rating the La Motte Chemical Products Company has. How accurate are its blood chemistry outfits and especially how reliable is the icterus index test as compared with standard methods?

M D Illinois

ANSWER—The various La Motte blood chemistry outfits have been designed for clinical use and probably answer this purpose very well, especially when a clinician is interested in the estimation of a single blood constituent. (The matter has been discussed in *Queries and Minor Notes* in *THE JOURNAL*, Nov 23 1929 p 1673 July 11, 1931 p 126 and June 4 1932 p 2011). The Icterus Index Comparator is a good illustration

of the principle used in most of these outfits. The method of R. C. Pigford (Simplified Apparatus and Technique for the Determination of the Icterus Index, *J Lab & Clin Med* 13:658 [April] 1928) is employed. A series of eleven bichromate standards equivalent to icteric indexes of 1, 2, 3, 5, 6, 7, 10, 15, 20, 25, 50 and 100, in small tubes of uniform bore, are employed for comparison against twenty drops of serum or plasma, obtainable from 3 to 5 cc of blood. Although one probably would not be able to determine the exact icteric index without diluting the serum, it should be possible to gauge the severity of any icterus present by comparison with these various standards.

#### WARTS ON EYELID

*To the Editor*—A girl aged 4, has five small warts on one eyelid. They are of the variety usually known as seed warts. They are not pigmented. Recently one has begun to show signs of irritation probably because the child rubs it unconsciously although the mother never has noticed her touching it. A roentgenologist has advised me not to use x-rays over the eye in view of the tarsal plate being present and also because of possible retinitis. Have you any references on removal of warts from such a location? There is no indication of their gradual disappearance; on the contrary, they are gradually increasing in size. Please omit name.

M D Pennsylvania

**ANSWER**—One or two very light applications of solid carbon dioxide will often make small warts disappear. The instantaneous application of a high frequency spark (electrodesiccation) may effect the desired result, also the instantaneous application of the actual cautery. Approximately 50 per cent of warts will disappear as a result of one or two intramuscular injections of sulpharsphenamine (0.1 or 0.2 Gm for a child) at intervals of one month. Weekly intramuscular injections of a bismuth compound (0.065 Gm for a child) for several weeks appears to be equally efficacious. In fact, injections of distilled water may suffice. Allington was able to obtain about the same results with distilled water as with other drugs indicating that the effect may often be psychic, which tends to corroborate the psychic experiments on warts conducted by the late Bruno Bloch and others and to explain the disappearance of warts after the application of various innocuous substances. Because of possible danger to the eyes it is preferable to avoid x-rays and radium. Acids, because of the difficulty of controlling the depth of action and of confining the application to a tiny area, might unnecessarily injure normal tissue.

#### DROWNING

*To the Editor*—Please give the most reliable method for examining the lung tissue from a body submerged in a river with the idea of determining whether the body was dead before being thrown in the water, or whether the victim was drowned by falling in the river. Please omit name.

M D Mississippi

**ANSWER**—By examining the lung tissue only, it may not be possible to tell whether death resulted from drowning or not in all cases, but if the microscopic examination reveals in the air passages and alveoli of the lungs particles of gravel, sand, dirt or vegetable material such as may be found in water or at the bottom of water, it would be justifiable to conclude that the person was alive when he entered the water.

#### ENLARGED THYMUS

*To the Editor*—Would you be good enough to enlighten me on the following problem. A man and his wife both in good health with no significant family history had a female child ten years ago. Five or six months after her birth the child developed symptoms of thymic asthma. Roentgenograms taken by a pediatrician showed an enlarged thymus. High voltage roentgen therapy was instituted with only fair results. She had periods of remission of varying lengths of time. Finally at the age of 5 a blood smear was taken and showed chronic lymphatic leukemia. The child died a year later of this disease. The problem I have at hand now is this. The mother is pregnant again (two months) and needless to say is markedly upset. She fears that this child will also have an enlarged thymus and the leukemia. Is there any connection between the thymic condition and the leukemia? What possibilities are there of this child being afflicted either with the thymus, the leukemia or both?

HENRY L. PELKUS M D Boston

**ANSWER**—There is no reason to suppose that the second child will also have an enlarged thymus, as this is not a hereditary condition. For the same reason the mother should be assured that the development of a leukemia is not to be expected, a pediatrician with a wide experience states that he has not come across two leukemias in the same family. There is no connection between the enlarged thymus and the subsequent development of leukemia.

## Book Notices

**Brucella Infections in Animals and Man Methods of Laboratory Diagnostics** By I Forest Huddleson Department of Bacteriology and Hygiene Michigan State College Introduction by Ward Giltner Dean Division of Veterinary Medicine Michigan State College Cloth Price \$2.25 Pp 108 with 24 illustrations New York Commonwealth Fund London Oxford University Press 1934

This concise, lucid and timely monograph is offered by the author as an aid to the laboratory worker in the study of *Brucella* (*Alcaligenes*) diseases. It is also designed to provide the clinician with an interpretation of the results derived from the use of laboratory methods of diagnosis. Huddleson defends the thesis that there are three separate species of *Brucella* organisms: *Brucella melitensis* (Bruce), the true host of which is the milch goat, *Brucella abortus* (Bang), the cause of infectious abortion of cattle, and *Brucella suis* (Traum), associated with swine infection. All three species are known to be capable of producing undulant (Malta) fever in human beings, either as the result of the ingestion of raw dairy products containing living organisms or by way of the skin through contact with infected animals and their excretions. Many students of the disease question the belief that there are three separate species of *Brucella*. The similarity of the morphologic appearance of the organisms, cultural characteristics, behavior in agglutinin-absorption tests, and the similarity of the diseases which they produce in human subjects lead many observers to conclude that the apparent differences in virulence, world distribution, nitrogen and dextrose metabolism, carbon dioxide requirements, growth behavior toward aniline dyes, and the differences in nitrate and nitrite reduction are explainable on the basis of host adaptation. The methods of isolation of the organisms, the pathology bacteriology and serology of the disease, in animals and man are adequately treated. The clinician will be particularly interested in the chapters that treat of the diagnostic significance of the allergic (skin-test) methods, the opsonocytotoxic test and the agglutination test.

**You Must Relax A Practical Method of Reducing the Strains of Modern Living** By Edmund Jacobson M D Cloth Price \$1.50 Pp 201 with 27 illustrations New York & London Whittlesey House McGraw Hill Book Company Inc 1934

This is a popular presentation of the material found in the author's 'Progressive Relaxation' and is intended primarily for the layman. Relaxation is advocated, in general, as an everyday remedy against the effects of strenuous modern living, and specifically as a means of curing or alleviating, by itself or in combination with other treatment a variety of conditions ranging from overactive nerves and sleeplessness to high blood pressure and mucous colitis. The author repeatedly points out the differences between his method and those employed by advocates of autosuggestion and similar cults. He encourages skepticism on the part of both the physician and the patient. He warns of the danger of self treatment and self training in relaxation, as one is often mistaken as to whether he has been successful and consequently may fall into wrong habits of tension. Real progress in relaxing can be determined only

by electrical measurements with a delicate and costly apparatus developed by the author. The book would be of great practical value if the author had already succeeded in "selling" his theory and practice of progressive relaxation to the medical profession and now wished to tell the lay public what it was all about. Unfortunately the only instrument that will differentiate between "cultivated" and "ordinary" relaxation is the one in the author's possession, and he clearly cannot take care of all the millions of people who "must relax." However, the book is of some educational value. It is well written in a facile conversational style and should prove of interest not only to laymen but to physicians as well.

**Bacteriologia** Pelo Dr José Pedro de Carvalho Lima Director do Instituto Bacteriologico de São Paulo Paper Pp 563 with illustrations São Paulo Sociedade Impressora Paulista 1933

This book is patterned after well known English and American textbooks on bacteriology. Jordan, Ford, Zinsser, Park and Williams, Topley and Wilson and many others are not only referred to frequently but the author handles the subject in much the same way as the English writers. The book is divided into five parts. The first or introductory part is a treatise on the bacteria in general. The second part discusses infection and immunity. This portion is concise and short. It touches only the most important aspects of this phase in bacteriology. The third part describes the salient characteristics of the pathogenic bacteria. The arrangement of this part is not as detailed, systematic or accurate as that found in English textbooks of bacteriology, the differentiating morphologic and cultural characteristics are not discussed in sufficient detail. Only the more common and well known pathogens are included, and closely related bacteria are omitted. In the genus *Mycobacterium*, for example, only the tubercle and lepra bacilli are described, and differentiating characteristics of other acid-fast organisms are not stated. The fourth part describes infectious diseases in which the causative organism is as yet undetermined. The author describes a "typhus exanthematicus of São Paulo" in which he has demonstrated "*Rickettsia brasiliensis*" in the endothelial cells in the peritoneum of guinea pigs inoculated with virus. In this fourth part a chapter on bacteriophage is included. The underlying principles are briefly discussed. The fifth part, consisting of only three pages, outlines the bacteria commonly found in milk and water. A supplementary portion describes the common pathogenic fungi and protozoa. This part is of little value to students or physicians, since the descriptions are too brief and there are no illustrations.

**Practical Pedodontia or Juvenile Operative Dentistry and Public Health Dentistry** An Introductory Text for Students and Practitioners of Dentistry By Floyd Eddy Hogeboom D D S Professor of Children's Dentistry College of Dentistry University of Southern California Special chapters by Forrest Anderson M D Sc D Director Child Guidance Clinic of Los Angeles and Pasadena Harold Hawkins D D S Thaddeus P Hyatt D D S F A C D Director Dental Department Metropolitan Life Insurance Co and Harry E Straub D D S Special Instructor in Exodontia and Minor Surgery Third edition Cloth Price \$6.50 Pp 327 with 209 illustrations St Louis C V Mosby Company 1933

This is intended as a textbook and reference authority for students and practitioners of dentistry for children. In his introduction the author properly emphasizes the importance of dentistry for children. He stresses the fact that all children require the consultation and assistance of a dentist and that adequate dental care in childhood would prevent a large proportion of the dental difficulties of maturity. The chapters on the management of children in the dental office and on mental hygiene, the latter by Forrest N Anderson are fully as interesting and important to those having the responsibility for the care of children as to the doctor. The fourth chapter, on embryology is a brief and sketchy outline of the early stages of embryologic development. Since most dental students have two years of preprofessional collegiate training, the inclusion of such a chapter in a textbook becomes less and less important. It cannot be made extensive enough to satisfy the demands of those who are interested. The fifth and sixth chapters are devoted to the growth and development of the individual as well as to the development of the teeth and dentures. These subjects are of great importance to all interested in the care of children and it is gratifying to see them occupying more space in such textbooks. In general the technical

chapters are excellent, included are cavity preparation, filling materials, roentgenography and the various operative phases of the subject. The directions with reference to extraction of the first permanent molars should be modified to emphasize the seriousness of the loss of this tooth. The sentence "The erupting second permanent molar will move forward and fill the space without tipping" (page 137) should either be removed or be modified. At present it leaves an erroneous impression. Dr Thaddeus P. Hvatt's chapter, based as it is on the examination of more than 12,000 persons, is worthy of careful consideration. The chapter of Dr Harold F. Hawkins, on prevention of dental caries by nutrition, is an excellent presentation of the work of this investigator. While the theoretical explanations may or may not be correct, his clinical methods are giving gratifying results in the control of dental disease. The chapter on endocrinology and its relation to dentistry summarizes the generally accepted beliefs in this field. The chapter on public health in dentistry deserves special commendation, especially is the inclusion of this subject in such a work to be commended. The book will be found interesting and profitable for students in this field.

*Les dilatations des bronches. Clinique pathogénie diagnostique et traitement.* Par Michel Léon Kündberg, médecin des hôpitaux de Paris. Paper. Price 22 francs. Pp 126 with 19 illustrations. Paris: Masson & Cie 1934.

This is an excellent presentation, in compact form, of the views of one of the highest authorities in France on the subject of bronchiectasis. For diagnosis the author advises the use of two methods: one, the introduction of iodized poppy-seed oil by the catheter passed through the nose; the other, bronchoscopy. Minute instructions are given for a special technic in the making of the roentgenograms. The advantages of bronchoscopy in the author's opinion are that it not only enables a diagnosis but gives valuable information as to the condition of the mucosa, the abnormalities at the bifurcation, the diameter of the bronchi at various levels, the pathology of the narrowings, and the presence or absence of neoplasms. In connection with the description of the clinical features the matter of treatment is carefully considered. The author's experience has been unfavorable with lobectomy except in extremely rare cases. Progressive emphysema is regarded as involving excessive risk, though occasionally curative. Collapse he regards as but rarely indicated. In the final paragraph the following statements are made: "Almost always bronchoscopic methods constitute the treatment of choice. It is palliative in most of the cases and if used early has resulted in definite cures without any risk. The technic of bronchoscopy is not given. The author is an internist who has seen much of the bronchoscopic work of Andre Soulas."

*Recent Advances in Psychiatry.* By Henry Devine, OBE, MD, BS, Medical Superintendent, Holloway Sanatorium, Virginia Water, Surrey, England. Second edition. Cloth. Price \$4. Pp 364. Philadelphia: P. Blakiston's Son & Company, Inc. 1933.

When the first edition of this book was reviewed, it was pointed out that it was an excellent summarization of the best of the tremendous literature in the fields of neurology and psychiatry. The same comment can be made of the present edition. The book serves as a worthy supplement to the conservative psychiatric textbooks and it is carefully done. As in the earlier edition, one finds that the organic and physiologic factors in the psychoses are chiefly stressed and there is much emphasis placed on those changes in the psychoses which may be artificially produced. The larger number of chapters deal with the infectious toxins and somatic factors as well as with somatic conditions in the psychoses. For some time the literature of psychiatry has been much in need of some of the material in this book, particularly that which summarizes such subjects as those discussed in part IV under the titles "blood sugar studies," "basal metabolism," "deficient oxidation," and "the psychogalvanic reflex." Some space is given to the biopsychic types and also to certain phases of psychology as applied to the psychoses. The last section deals chiefly with psychology from the Freudian point of view, with an occasional mention of Jung. Psychotherapy, child psychiatry and nursing are but briefly touched on, but this brevity is only to be expected in view of the obvious limitations of space imposed

on the writer of a book such as this one. All in all, the book remains an excellent summary of the literature, and the new chapters and paragraphs that have been inserted have added greatly to the usefulness of this study. The leaning toward the organic, which has been mentioned as characterizing this volume, is excusable in view of the fact that there is a companion volume treating of the psychoneuroses.

*Science and Sanity. An Introduction to Non-Aristotelian Systems and General Semantics.* By Alfred Korzybski. Cloth. Price, \$5.50. Pp 798 with illustrations. International Non-Aristotelian Library Publishing Company, Lancaster, Pennsylvania. Science Press Printing Company, 1933.

In spite of its title, this book is neither scientific nor sane, it is merely ponderous. It is the first volume of a series of books dealing with non-Aristotelian logic. As the volume runs to almost 800 pages it is not susceptible to summarization, particularly since it is so abstract. The chief principle of Aristotelian logic is an attempt to find similarities, and the present author criticizes this saying that abstractions should be found, and hence that the most valid science that can be brought to bear on life is mathematics. He feels that mathematics is a group of patterns of relational language, which reveals at its various steps the workings of the human mind, and he stresses the fact that much of the difficulty that the human mind experiences is in grasping meanings which he calls "semantic structures." The entire book is a combination of various abstruse interpretations of linguistics and mathematics, which will be found rather difficult of comprehension for one who is not trained in logic—and algebraic logic, at that. This author's information is derived from such varied sources as Aristotle and Niels Bohr, Isaac Newton and C. S. Sherrington and William A. White. Since he points out that mental adjustment is a purely linguistic matter, this author would seem to be well adjusted, but to the psychiatrist there seems to be little of value in the book. There are vast chapters dealing with abstruse mathematical problems and others treating of linguistics, only two of which can be definitely tied up with psychiatry and these only from the aspect that they represent a summing up of such ideas about the nervous system as may bear a relationship to the author's theories. However, future issues, which are to discuss more specific subjects, may add something to make this type of thinking more palatable.

*Beiträge zur Kenntnis der septischen Pleuraempyeme unter besonderer Berücksichtigung der Spätergebnisse.* Von Evert Schildt, Med. Lic. Inaugural Dissertation zur Erlangung der medizinischen Doktorwürde. Uppsala. Paper. Pp 205 with illustrations. Uppsala: Almqvist & Wiksells Boktryckeri, a. b. 1931.

This monograph, which is an inaugural dissertation with a selected bibliography, consists of a general discussion of type, etiology, pathogenesis, diagnosis, bacteriology, complications and treatment of acute and chronic empyema and their complications, with results as to permanent healing, recurrence, causes of death and degree of rehabilitation. It includes 289 case reports. The treatment for the most part was by open drainage by means of subperiosteal rib resection or intercostal incision. In seven cases immediate symptoms were suggestive of acute collapse of the lung with mediastinal flutter. Four of these patients died shortly following operation. The closed method of drainage was used in only four cases. The total mortality was 18.6 per cent. The study is thorough, systematic and comprehensive and is well worth careful perusal by those interested in the subject.

*The Hospital Manual of Operation.* By Warren P. Merrill, Ph.D., M.D. Cloth. Price \$3. Pp 315 with 19 illustrations. New York: Lakeside Publishing Company, 1934.

This contains chapters on organization, staff organization, planning and construction, admission and discharge procedures, purchase and issuance, nursing department, dietary department, housekeeping, mechanical department, special equipment, clinical records, fire protection, accounting and public relations. The author gives a valuable discussion on each of these subjects. The book does not pretend to be a complete guide for any single job in the hospital. It gives a great deal of information not included in similar works. The bibliography at the end of each chapter should be of assistance where the works referred to are available.

## Medicolegal

**"Mariguana" Defined**—The defendant, Navaro, was convicted on an information charging him with possessing marihuana, under the Utah statute providing that

'It shall be unlawful for any person firm or corporation to sell furnish or give away or offer to sell furnish or give away or to have in possession any cocaine opium morphine codeine heroin peyote (mescal button) alpha eucaine beta eucaine nova eaine flowering tops and leaves extracts tinctures and other narcotic preparations of hemp or loco weed (cannabis sativa Indian hemp) marihuana or chloral hydrate or any of the salts derivatives or compounds of the foregoing substances or any preparation or compound containing any of the foregoing substances, or their salts derivatives or compounds excepting upon the written order or prescription of a physician dentist or veterinary surgeon licensed to practice in this State *Comp. Laws Utah 1917 Sec 4432, as amended by Laws of Utah 1927 Ch 65*

On appeal to the Supreme Court of Utah, Navaro contended that the term "mariguana," as used in the statute, signified a plant, not a drug, that the statute did not forbid the possession of "mariguana" but forbade only the possession of its flowering tops and leaves and the tincture, extract, and other preparations of it, and that therefore the possession of "mariguana" was not an offense under the statute.

The word "mariguana," said the court, is not found in most of the ordinary dictionaries of the English language and is not directly defined in any of the medical or scientific dictionaries available to the court. It is not a scientific name either of a plant or a drug, but is a word in local use, of comparatively recent origin in the United States. Several variants of the word are in use, all meaning the same thing, as marihuana, mariahuana, marajuana, maraguana, and marihuana. The growing body of literature with respect to marihuana and its uses is found in magazines and newspapers, rather than in scientific works. The Encyclopaedia Britannica, edition 14 volume 2, page 420, however, correlates marihuana to cannabis when it defines hemp as cannabis sativa and says

Other forms are cultivated for the narcotic drug cannabin known in different forms and in different countries as hasheesh blang gunga charras, kif and marijuano in India Arabia, Africa and Mexico.

Terry and Pellens, in "The Opium Problem," 1928, page 809, make a similar correlation, saying

More recently another group of drugs has found its way into the anti narcotic laws of a number of the states. This group is included under the genus of cannabis sativa which includes the two species cannabis indica and cannabis americana. This drug is also known under the Spanish name of *Marihuano*.

The use of the word marihuana by physicians, chemists and police officers, and by persons who smoke it, has been recognized by the Supreme Court of Utah in *State v Diaz*, 76 Utah 463 290 P 727, wherein the court quoted at length the testimony of a physician regarding the nature and effects of the preparation, and it was referred to again in *State v Franco*, 76 Utah 202, 289 P 100. In *State v Bonoa*, 172 La 955, 136 So 15 the defendant, charged with having possession of plants known as marajuana, under a statute making it unlawful to possess such plants, contended that there was no such plant and that the terminology of the statute conveyed to the people no conception of what was prohibited. But the court said

We do not find any difficulty in holding that the use of the word marajuana in connection with the word plant conveys to the mind exactly what the Legislature intended to convey namely the plant scientifically known as Cannabis Indica or Cannabis America [sic] though there possibly may be some slight and unimportant botanical difference between the two but apparently none in its effects upon the human system. It is true that the word is not found in dictionaries ordinarily used but it is found in the American Illustrated Medical Dictionary where it is spelt Mariahuana and in the Encyclopedia Britannica (1929 14 Ed) in the article on Hemp where it is spelt Marijuana and in the statutes of at least two other states namely New Mexico where it is spelt Mariguana (Chapter 42 of Laws of New Mexico 1923 p 58) and Texas where it is spelt Marijuana (Vernon's Annotated Criminal Statutes 1925 vol 2 Pen Code chapter 3 art 720). In these statutes the word seems to be used in reference to some drug or preparation from the plant Cannabis Indica or Cannabis [sic] Sativa. However the application of the name of the drug or preparation to the plant as for instance the plant known as Marajuana could hardly be misleading even assuming that the word more properly refers to the drug or preparation than to the plant itself.

Laws of Colorado 1927, chapter 95, section 1 page 309, refer to "Cannabis Indica, or Cannabis Sativa, commonly known

as Indian Hemp, Hasheesh, or Marijuana." The Texas statutes (Complete Texas Statutes, 1928, art 720, p 1107 [Vernon's Ann P C, art 720]) refer to "cannabis (cannabis) indica, cannabis (cannabis) sativa or preparations thereof or any drug or preparation from any cannabis (cannabis) variety, or any preparation known as marijuana." Laws, New Mexico, 1923, chapter 47, section 1, page 58, refer to "cannabis [sic] indica, also known as hashish and marijuana." The Montana Statute (Rev Codes Mont, 1921, sec 3186, as amended by act of March 8 1927, ch 91, sec 1) refers to "mariahuana (Cannabis Indica)." In the *American Journal of Police Science*, volume 2, page 257, Eugene Stanley, district attorney, parish of Orleans, New Orleans, says

Marihuana is the Mexican term for Cannabis Indica. The plant or drug known as Cannabis Indica or Marihuana, has as its parent the plant known as Cannabis Sativa.

It would seem said the Supreme Court, that the word "mariguana," when used without modifying words, indicates the product or preparation consisting of the flowering tops leaves and seeds of Cannabis sativa, rather than either the whole plant or the fibrous stocks thereof. Although it is used indiscriminately in some articles with reference to the plant, the drug or the flowering tops and leaves of Cannabis sativa, the preponderant use of the word, the court thought, clearly had reference to the product used for smoking. That use was so frequent and common that when the statute prohibited the unauthorized possession or sale of "mariguana" as a drug, no one could misunderstand its meaning. The information under which the defendant was convicted charged the unlawful possession of "mariguana," in the language of the statute, and that was sufficient.

The contention of the defendant that he had been erroneously convicted because the state had not proved that he did not possess the marihuana found on his person, on the written order or prescription of a licensed physician, dentist or veterinary surgeon, the court held to be without merit, quoting 49 C J 1053.

Where the statute relating to poisons or narcotic drugs contains exceptions a defendant desiring to avail himself of any of them by way of defense must show that he comes within its intent. Thus the burden is upon one accused of illegal possession to show that his possession was lawful under a proviso or exception of the statute under which he is being prosecuted.

The judgment of the trial court was affirmed—*State v Navaro (Utah)*, 26 P (2d) 955.

## Current Medical Literature

### AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending, but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (\*) are abstracted below.

**Bacillus Alkaliscens a Variant of Bacillus Typhosus**  
—Gilbert and Coleman offer information concerning eight cases of typhoid. Cultures of both Bacillus typhosus and B alkaliscens were isolated from specimens from these patients. One of the cases represents a laboratory infection. The patient had been handling cultures of both species. Although typhoid bacilli were readily obtained from this patient's blood during the first two weeks of illness they were isolated with difficulty from the early fecal specimens while B alkaliscens was apparently present in relatively large numbers. Later both types were numerous, and finally neither was found. The significance of B alkaliscens in this case can only be conjectured. Its presence previous to the illness is unlikely, since it persisted and disappeared at about the same time as the typhoid bacilli. Therefore it can be concluded that either a strain of B alkaliscens may have been the incitant which after entering the body, developed into a true typhoid bacillus, or, if B typhosus was ingested, the other species may have been its variant. The authors show that strains of bacteria having the properties of B alkaliscens are present in approximately 1 per cent of all specimens submitted for bacteriologic examination for evidence

of enteric disease. Clinical and epidemiologic data suggest a close relationship to the typhoid bacillus. In the study of specimens from patients recovering from typhoid and in the search for carriers, the presence of this type of micro-organism seems of special import. Even though, in itself, it may have no pathogenic significance, the fact that in so many instances B typhosus has been isolated from the same or other specimens from the person concerned makes a thorough search for this micro-organism imperative, whenever strains of B alkaliscens are found. When suspected typhoid carriers are concerned, it would seem important to examine a large series of fecal specimens and, if possible, duodenal contents.

**Chicken Embryo Cultures for Immunization Against Smallpox**—Coffey states that vaccine virus, when cultivated for long periods in a medium consisting of minced chicken embryo tissue suspended in Tyrode's solution, gradually decreases in potency according to the cutaneous reactions induced in rabbits. The potency of the culture virus can be regained by passage through the testicles of rabbits. Vaccines prepared from chicken embryo cultures can be stored at low temperatures for considerable periods without loss of potency if air is excluded. Children vaccinated with culture vaccine developed characteristic primary vaccinia, but the proportion of takes was lower than that among children vaccinated with calf lymph, when either the multiple puncture or single scratch method is used. Since the culture vaccine is both potent and stable, further study should be carried out to determine a method of preparing it for distribution so that it will equal calf lymph in efficacy.

**Roentgen Ray as Aid in the Diagnosis of Hemophilia**  
—Rypins presents three cases of hemophilia, with comments on other cases in the literature, which, in his opinion, all showed characteristic changes in the roentgenograms. These roentgenograms revealed marked widening and deepening of the intercondylar fossa, with arthritic changes in the remainder of the joint. The blood supply in the knee joint enters at the intercondylar fossa. Klason considers that bleeding occurs at the point of attachments of the crucial ligaments, at the apex or the intercondylar fossa. Bleeding causes bone deterioration, and it is conceivable that the pressure from the bleeding would cause erosion, at this point, since at the apex of the intercondylar fossa there is no cartilage. However, Key believes that possibly intra-osseous hemorrhage plays an important part. While in tuberculosis of the knee joint there may be some widening and deepening of the intercondylar fossa it does not reach the extent that it does in hemophilia and there is apt to be more destruction of cartilage. Proliferative changes are readily explained by the receding hemorrhages. Since trauma is supposed to be the exciting cause of the hemorrhages, the knee joint is the most logical to study as it is more exposed to trauma and apt to show the more advanced changes. Hemorrhagic purpura sometimes causes bleeding into the knee joint but apparently does not cause enough bleeding to bring about changes demonstrable in the roentgenogram. Low grade infectious arthritis may cause widening and deepening of the intercondylar fossa,

although not commonly, but in this type of condition, in the cases which the author observed, there is apparently no proliferation. The hereditary history and the ordinary laboratory observations would, of course, tend to rule out other conditions. Klason considers the enlargement and widening of the intercondylar fossa an especially distinct feature of hemophilia. The one patient who received ovarian extract has done remarkably well. Heuffer reports that irradiation of the spleen has given some temporary benefit, on the basis that thrombokinase has been liberated.

**Radon Ingestion and Its Possible Health Dangers**—Barker points out that the exposure of an operator in a dial painting laboratory to the emanation in the atmosphere of the laboratory does not in all probability constitute a hazard. Based on typical working conditions the exposure to alpha rays is no more than it would be if 0.00004 microgram of radium element was permanently deposited in the system, a quantity insignificant in comparison with the safe tolerance of the individual. Alpha radiation resulting from the polonium formed from the active deposit is at the best nominal and probably about 2 per cent of the alpha radiation produced by the radon. The chances for any accumulation of the active deposit of slow change in the system are practically nil. The possibility of any harmful effects resulting from the ingestion of radon as administered therapeutically either by inhalation or by injection is remote.

**Desiccated Hog Stomach, Liver Extract and Raw Liver in Experimental *Endamoeba histolytica***—Following a preliminary test of the benefit of feeding raw liver to dogs infected with *Endamoeba histolytica*, Faust and Kagy compared the relative efficacy of desiccated hog stomach, desiccated liver extract and raw liver, fed by mouth to infected dogs. The series includes five positive animals inoculated intracably with human strains of *E. histolytica*, subsequently treated with desiccated hog stomach, five positive animals, similarly inoculated and subsequently treated with desiccated liver extract, and nine animals, similarly inoculated, of which seven were treated with raw liver before inoculation and two after infection was established. Ninety-four dogs similarly infected but untreated and others uninfected were used as controls. Desiccated hog stomach was found to be consistently harmful to the host, not only being ineffectual in checking the invasion of the amebas but actually reducing the resistance of the tissues of the wall to secondary bacterial invasion. Liver extract was found to be beneficial to the host, and it appreciably arrested the amebic process. This was indicated by the improved appearance of the animal, the tendency toward formed stools with sluggish or encysted amebas and the evidence of repair of the damaged tissues on gross and microscopic post-mortem examination. In most animals, however, the control was only partial and never produced spontaneous cure. Raw liver was found to be helpful in arresting the amebic process and in certain cases produced complete eradication of the pathogenic organism. Clinical "cure" is not conclusive evidence of complete eradication of the amebas. The evidence suggests that the efficacy of the liver feedings consists not in its stimulating action on the hematopoietic organs but by direct contact with the tissues which the amebas attack. It is not amebicidal but amebastatic. Growth and multiplication of the amebas are arrested; they may encyst in the tissues as well as in the lumen of the intestine, and the healing process is appreciably activated. The tendency of liver to neutralize the toxic effects of histamine and other degeneration products of proteins in the lumen of

the intestine conceivably aids the healing process and reduces the danger of bacterial invasion.

**Carbarsone Rectally in Amebiasis**—Anderson and Reed began treatment in twelve cases of amebiasis by instilling into the rectum, after a cleansing enema, 200 cc of a 2 per cent solution of sodium bicarbonate containing 1 per cent carbarsone. A rapidly acting sedative, such as sodium amylal orally in a dosage of 0.2 Gm., was given beforehand to induce sleep and allow the patient to retain the drug overnight, if possible. If the retention enema was expelled during the night, the treatment was repeated until at least five enemas were retained overnight. Usually this procedure was attempted on alternate nights until 10 Gm of the drug had been given. In the majority of cases prompt symptomatic relief followed. It was not necessary to place the patient in a hospital except when he could not be cared for at home. Since the treatment was given at night, it did not interfere with the usual daily activities of the patient. No untoward symptoms or contraindications to the method were noted. Dysenteric symptoms were relieved by using carbarsone rectally, but amebas were not eradicated completely. Oral therapy was resorted to, and eight of the group received the usual dosage of 5 Gm of carbarsone in ten days, given twice a day in gelatin capsules containing 0.25 Gm of the drug. In two cases this course was repeated, and in two more a third series of capsule administration was necessary. Other drugs were tried in combination with carbarsone. Seven of the group received adjuvants in addition to carbarsone rectally, and the stools of five of these remained negative during an average follow-up period of five and one-fourth months. The remaining five who had been given carbarsone alone, orally and rectally, were ameba free during the observation period. From three to six daily stool specimens were examined every two to four weeks during this period. Special search failed to reveal evidence of drug toxicity in any patient. No kidney, liver, eye or other damage from carbarsone was noted. Sigmoidoscopic examinations of nine patients following therapy revealed ulceration of the mucosa of the sigmoid area in only one case. This patient had been refractory to all forms of therapy tried over a period of twelve months but was clinically improved and had gained 7.5 Kg during the year of observation. Weight gains occurred in more than half of the series, and the symptom response was favorable in every case.

**Untoward Effects of Antiamoebic Drugs**—Anderson and Reed point out that emetine hydrochloride is toxic for most mammals, including man, in total doses from 10 to 25 mg per kilogram of weight. The heart muscle bears the burden of the toxic effect. The maximal safe total dose of emetine hydrochloride is 10 mg per kilogram of weight in patients with an amebic hepatitis and free from heart damage. No untoward effects have been observed with the use of the kurchi alkaloids. Acetarsone may exhibit toxic manifestations in one of every six cases treated. The case of a patient showing intolerance to 5 Gm of this agent taken over a period of twenty-eight days is reported. Acetarsone, in the authors' opinion, is too toxic for routine clinical use. Animal experiments emphasize this point. Carbarsone has been given to 330 patients in total doses (orally and rectally) ranging from 75 to 2,100 mg per kilogram of weight in divided amounts over a period of fifteen months. A single instance of intolerance is reported in a patient with acute hepatitis who had an untoward reaction to 5 Gm of the drug given in ten days. An arsenical should not be given in the presence of hepatitis. Slight gastric distress has also been noted, but no evidence of damage to the kidneys, optic nerve, skin or other tissues has been observed. Liver damage has been reported elsewhere from the use of chiniofon, but the authors have abandoned this agent because of its relative inactivity as an amebicide, using vioform in preference to chiniofon. Three of sixty patients given the drug orally in doses ranging from 100 to 1,000 mg per kilogram of weight over a period of twelve months have experienced gastric and other distress but no other definite untoward effects. The drug cannot be used rectally because of local irritation. Since the soluble hydrochloride of vioform causes local effects on mucous membranes, it is possible that a gastric hyperacidity may be responsible for the distress experienced by these three patients. Enteric coated capsules

may eliminate this difficulty Bismuth subnitrate may cause methemoglobinemia and on this account the use of bismuth subcarbonate should be avoided Heptylresorcinol irritates the mucous membrane of the gastro enteric tract and is not to be recommended as an anebralide until more adequate data on its efficiency are available

Certain Aspects of Pulmonary Tuberculosis in Children with Especial Reference to Prognosis R Morgan Westfield Mass —p 577

**Anatomic Changes in the Diaphragm Following Phrenicectomy**—Stanbury gives an analysis of eleven cases of atrophy of the diaphragm following section of the phrenic nerve In all but one case the operation of choice was evulsion by the method of Fell The duration of the paralysis varied from three weeks to six years Atrophy of the diaphragm was evident as early as the third week after section of the phrenic nerve and was complete by the fourth month After paralysis, one half of the diaphragm was elevated and everted into the thorax With stretching it became a thin whitish membrane of parchment-like thinness Histologically the atrophy of the paralyzed half of the diaphragm was seen to be complete and uniform In one case a few normal muscle bundles were seen in one area, scattered among atrophic fibers This probably represented an accessory nerve supply rather than actual regeneration In view of the marked distortion of the abdominal viscera in ten of the cases, in three of which there was a fatal gastroduodenal obstruction, the author points out that the possibility of such complications must be considered when advising phrenicectomy for the treatment of pulmonary disease

**Shifting Electrical Axis of the Heart in Artificial Pneumothorax**—Treiger and Lundy studied the shifting of the electrical axis of the heart measured by Einthoven's "triangle" in correlation with roentgen observations on the positional changes of the heart in thirty-one cases, seventeen presenting left and fourteen right pneumothorax They observed that artificial pneumothorax without adhesions or fluid whether left or right, shifts the electrical axis to the right The heart is displaced to the right by left pneumothorax and to the left by right pneumothorax This displacement may be independent of the shifting of the electrical axis The degree of shifting of the electrical axis in pneumothorax is in direct proportion to the quality of the pneumothorax The average shifting of the axis to the right is greater in left than in right pneumothorax Adhesions in pneumothorax may prevent the usual shifting of the electrical axis to the right in whole or in part, and may be associated with shifting of the electrical axis to the left The degree of shifting of the axis in pneumothorax with adhesions is influenced by the location quantity and quality of adhesions as well as by the quality of pneumothorax Adhesions usually prevent the production of a complete and excellent pneumothorax and are associated with a partial pneumothorax of a lower grade thus diminishing or eliminating the factor of pneumothorax Fluid in pneumothorax, similar to adhesions frequently is associated with shifting of the electrical axis to the left This may be due to the presence of adhesions However, it was seen that fluid without demonstrated adhesions also was associated with shifting of the axis to the left Fluid in pneumothorax similar to adhesions, influences the quality of pneumothorax and frequently changes it from a complete and excellent pneumothorax into one of partial and of lower grade Adhesions

develop frequently, especially after a partial absorption of fluid, and their action may overshadow the two other factors—pneumothorax and fluid

\*Heredity in Arterial (Essential) Hypertension Clinical Study of Blood Pressure of One Thousand Five Hundred and Twenty Four Members of Two Hundred and Seventy Seven Families D Ayman Boston —p 792

**Metabolic Exercise Tolerance Test**—Soskin and his associates outline the following method for determining the excess oxygen consumption during exercise and the time required for recovery by the metabolic exercise tolerance test The spirometer is filled with oxygen from the first tank and if desired, the oxygen consumption during rest is determined or a basal metabolism test may be performed in the usual manner When this is completed the clockwork drum is stopped and the spirometer is refilled from the first tank By means of a fine needle valve oxygen is introduced into the spirometer from the second tank through the flowmeter at such a rate that the writing point continues to superimpose its record at the same constant expiratory level The clockwork drum is now restarted and the record is observed for several minutes to ensure the existence of an exact balance between the oxygen consumed by the resting patient and the oxygen introduced from the second tank Once this exact balance has been established the adjustment of the needle valve is left unchanged for the duration of the test Reading of the flowmeter offers an additional visual check on the constancy of the supply of oxygen at all times With the oxygen flowing into the spirometer at a rate equal to the oxygen consumption during rest the exercise of lifting two 2625 Gm weights through a distance of 375 cm at a rate of twenty times a minute for two minutes is performed and the observations are continued until a new constant expiratory level is recorded The difference in height between the constant horizontal levels, before and after exercise, represents the excess oxygen consumption during the exercise The time elapsing from the end of the exercise

to the point at which the final horizontal level is first established represents the time required for recovery. The difference between the horizontal lines may be read directly from the ruled paper in millimeters and converted to cubic centimeters of oxygen by multiplying by the conversion factors 20.73. The volume of gas is corrected to standard temperature and pressure in the usual manner.

**Heredity in Arteriolar Hypertension**—Ayman made a study of the blood pressure, height and weight of 1,524 members of 277 families. Of 780 members, aged from 14 to 39 years, of the second generation of the families, elevated systolic and diastolic blood pressure readings (140 systolic and 80 diastolic, or higher) occurred in 148 subjects. These subjects had the same average age and sex incidence as the entire group of 780 children, but they were  $14\frac{1}{10}$  pounds above the average weight compared to  $4\frac{1}{2}$  pounds above the average weight for normal children. The families studied were then grouped according to the presence or absence of arteriolar (essential) hypertension in one or both parents. In the families whose parents had absolutely normal blood pressures the incidence of elevated blood pressures in the children was only 3.1 per cent. In the families in which both parents had arteriolar hypertension the incidence of elevated readings in the children reached to 45.5 per cent. Of seventy brothers and sisters of parents with normal blood pressures 37.3 per cent had elevated blood pressure readings whereas of eighty-six brothers and sisters of parents with arteriolar hypertension 65.3 per cent had elevated blood pressure readings. Of eighteen families in which parts of three generations were available, the results were similar to those of the foregoing seventy brothers and sisters. The results presented show that there is an unusually high incidence of elevated blood pressure readings in the children, brothers, sisters and parents of subjects with arteriolar hypertension, as compared with similar relatives of subjects with normal blood pressure. These results are strong evidence for the existence of a hereditary factor in arteriolar (essential) hypertension.

**Transurethral Surgery**—Caulk is convinced that transurethral surgery should be employed in at least 80 per cent of all vesical neck obstructions benign and malignant and that it could be employed in practically all obstructions but for his belief in the necessity for repeat operations. In dealing with prostates of tremendous dimensions he does not feel justified if the subjects are good surgical risks in subjecting them to such a long course of corrective transurethral procedures, but he thinks that these glands should be removed surgically. In the poor surgical risks the aim should be to give them a maximal result with a minimal sacrifice and this can be done only through repeated transurethral procedures over a long period. Transurethral surgery is indicated in practically all cancers of the prostate usually in conjunction with radium or high voltage roentgen therapy, polyps or congenital bands in the urethra, contractures of the neck in women and children as a complication of vesical tuberculosis and to close indolent suprapubic fistulas. The punch operation of the cautery type, such as the author's, or associated with coagulation is far superior to any of the electrical devices at present employed. He describes a modification of the cautery punch that meets the demand for a visual instrument which will remove tissue with the highest degree of safety.

**Calorigenic Action of Thyroid**—Lerman and Harington and an intermediary substance for comparing the physiological action of various types of thyroid substance. Daily oral administration of 0.5 mg of iodine in this form in five cases of myxedema produced approximately the same average daily intravenous injections of 0.5 mg of iodine in form into such patients. A single curative dose of iodine as polypeptide in two cases of myxedema s intravenous route somewhat more effective than the oral large dosage. On the other hand, intravenous polypeptide single large dose duplicated the effect of crystalline iodine given intravenously in equivalent dosage. Since the polypeptide is optically active and the crystalline thyroid racemic, it follows that neither optical activity nor linkage enhances the physiologic potency of thyroxine effect of whole gland was tested by daily oral administration of desiccated thyroid. In three cases of untreated myxedema patients reacted more rapidly than the standard reference dose was adjusted to 0.5 mg of thyroxine iodine. Four other patients received from 0.69 to 0.77 mg of total iodine in the form of desiccated thyroid. The response of five patients receiving 0.42 mg of total iodine daily in the form of desiccated thyroid was slightly less than that of the control group. Comparative studies of the maintenance dose (in terms of iodine) of six lots of commercial thyroid in twenty cases of myxedema indicated that total organic iodine rather than thyroxine iodine was important. The results indicate that all the iodine in thyroglobulin is calorigenically active. They also indicate that thyroid substance should be assayed in terms of total organic iodine rather than thyroxine iodine. The significance of total organic iodine holds quantitatively not only for whole gland but also for thyroglobulin and the smaller degradation products. Assays of thyroxine one patient having

toxic colloid' glands on two patients having myxedema indicated an effect that was better referred to the total organic iodine than to thyroxine iodine. Thyroxine peptone obtained by peptic digestion of human thyroglobulin gave similar results in two cases, whereas diiodotyrosine peptone previously fed to these patients, produced no metabolic effect. Therefore the results suggest that diiodotyrosine iodine is calorigenically potent so long as it is part of the thyroglobulin molecule but loses its activity when separated from the thyroxine iodine fraction.

**Weight Changes in the Suprarenals**—Blumenfeld studied the suprarenals from 176 rats to determine the effects of dietary modifications on the estimated weights of the cortex and the medulla of the suprarenals. Weights were estimated from serial sections by the paper outline method and it was shown that sections taken at 240 micron intervals gave average results not significantly different from those with sections at 10 or 15 micron intervals. The first pregnancy in normal Wistar albino rats did not alter the weight of the cortex or the medulla. Rats deprived of vitamin E and killed during the second pregnancy had suprarenals the cortex of which was questionably hypertrophied but the medulla of which was definitely atrophied. Rats maintained on a vitamin E deficient diet and carried through a first pregnancy then refed vitamin E and killed during a second pregnancy had significantly enlarged suprarenals, owing entirely to cortical hypertrophy. The medulla returned to a normal weight. A fat-free diet produced in male and female albino rats a relative atrophy of the suprarenals, because of both cortical and medullary decrease. Curing the symptoms of this diet by feeding fatty acids, chiefly linoleic did not cause a return of the suprarenal weight to normal. The weight of the medulla did increase but the cortical weight remained practically unchanged. The differences between the cortex and the medulla of the various female groups were statistically significant, none of those in the male groups except the subnormal weight of the medulla in the test group, were significant.

**Hyperglycemia Previously Attributed to the Anterior Pituitary-Like Principle**—The experiments of Davis and his associates reveal that the hyperglycemia produced by injection of urine into rabbits is due to urinary constituents other than the anterior pituitary-like principle that is uric and hippuric acids and possibly other substances. It cannot be elicited in pseudopregnant rabbits or in rabbits that have received massive doses of follicular hormone. It depends on the presence of the suprarenal medulla even though it does occur when the suprarenal medulla has been deprived of its thoracolumbar sympathetic innervation.

**Differentiation of Hemolytic Streptococci by Precipitin Tests**—According to Edwards, it was possible to differentiate hemolytic streptococci of human and animal origin by the precipitin test when acid extracts of the organism were used as antigens. *Streptococcus equi*, type A animal streptococci and type B animal streptococci all belong to the same serologic group. Streptococci of human origin constitute a second group. No cross reactions occurred between the two groups.

**Leukocytes in Immunity to Herpes**—The experiments of Jamuni and Holden, on rabbits, suggest that leukocytes have a definite tropinizing function in destroying herpes virus in the presence of immune serum. Both normal and immune cells aided in the inactivation of the virus in the presence of immune serum when the latter alone was present in an amount insufficient to neutralize the virus. At times results almost equally good were obtained with immune cells in the presence of normal serum, which suggests that leukocytes or possibly tissue cells, may be even more important than the serum antibodies in active herpes immunity. Mononuclear cells are more efficacious than polymorphonuclear cells in the disposal of herpes virus. The authors believe that the enhancing action is due to phagocytosis of the opsonized virus although this statement cannot be verified lacking demonstration of whatever morphologic unit constitutes the virus. Their experiments indicate that immune or normal phagocytic cells bring about a greater virucidal effect than can be obtained with immune serum alone.

**Cataphoresis in Prevention and Treatment of Infections of the Respiratory Tract**—According to the obser-

inations of Rosenow, vaccines prepared from strains of streptococci isolated in studies of influenza and preserved in glycerin salt solution suspensions have been shown to be harmless and to have well marked antigenic, preventive and curative powers against the common cold, influenza and other acute and chronic streptococcal infections of the respiratory tract. These results are in accord with those obtained in prophylactic inoculations against pneumonia during the pandemic of influenza of 1918 to 1920. Cataphoresis has been found useful in controlling the specificity of the streptococcus as found in various infections of the respiratory tract and as incorporated in vaccines. Experimental basis for the commonly observed early good effects from the use of the vaccine in treatment is afforded by the markedly increased destruction of streptococci in the peritoneal cavity of mice, due, it would seem, to altered cellular response or "immunity" induced by intraperitoneal or subcutaneous injection of the vaccine twenty-four hours before

**Specific Agglutinins in Serum Following Inhalation of Pneumococci**—Stillman states that, when rabbits are repeatedly exposed to a spray containing type I pneumococci type specific antibodies appear in the blood. In the experiments that he reports, agglutinins could be demonstrated in the serums for only a short period after the course of exposures was terminated. Protective antibodies, however, persisted for long periods, even for several years. When rabbits were repeatedly exposed to a spray containing virulent type II pneumococci, protective antibodies could be demonstrated in the serums for only relatively short periods of time, while agglutinins were only occasionally found to be present. When rabbits are repeatedly allowed to inhale cultures of rabbit-virulent type III pneumococci, type specific immune bodies do not appear in the blood. The immunity reaction exhibited by rabbits which have repeatedly inhaled a spray containing live pneumococci differs in different animals, depending to a considerable extent on the type of pneumococcus employed in the experiment.

**Justifiable Addiction and Nerve Block**—Lichtenstein and Greene are of the opinion that nerve block holds great promise as a substitute for agencies employed to allay unusual sensory disturbances because it gives relief in painful conditions. In certain diseases, it is certainly an aid in effecting a cure. Nerve block suggests a means of treating diseases of narcotic addiction. The authors are engaged in a series of experiments which, they hope, will finally solve the problem of scientific treatment

of addiction. They have cured people who became addicted because of certain painful conditions. They have followed some such cases for several years and are satisfied that these people have no desire for narcotics and are permanently cured of addiction.

**History of Tularemia Treated by Neoarsphenamine**—Shellhorn and Beckwith say that blood taken early in their case of tularemia treated with neoarsphenamine did not show Bacterium tularense. Six injections of 0.45 Gm doses were administered. The initial lesions began to improve noticeably within three days after the first injection. The right axillary gland ceased draining within twenty-four hours after the administration of neoarsphenamine at the second admission. The infection was caused by the bite of a squirrel. Infection with tularemia from the bite of an animal is most unusual. Members of the Forestry Service state that no other case of tularemia has come to their attention.

**Use of Ergotamine Tartrate in Migraine**—Lennox administered ergotamine tartrate by intravenous or subcutaneous injection to forty-five patients who gave a history of migraine, while they were having a headache. Abrupt termination of the initial attack treated occurred in forty patients. Eight of the patients had had frequent, incapacitating headaches for many years, had not found relief by other drugs or treatment and have used ergotamine tartrate for six months or longer. Seven of these have had almost uniform relief for individual attacks. Of these seven, four are having attacks at more frequent and three at less frequent intervals than before medication was started. The recommended single dose is 0.5 mg subcutaneously or 1 mg orally. Because patients vary in their reaction to the drug, it is wise to give but half the full subcutaneous dose at the first trial. If this is well borne but not effective, the full dose can then be given. The dosage can be repeated after an interval of from two to three hours. For a prompt sustained effect, the author prefers to give 0.5 cc (0.25 mg) intravenously and at the same time, the same amount subcutaneously. The dose should be varied in order to find the least amount that is effective. It is presumably more effective if given early in the attack.

**Paraldehyde for Control of Pain and Convulsive States**—Johnson found the intramuscular use of paraldehyde beneficial in various maniacal and convulsive cases in which morphine failed to give relief. He considers 8 cc an average dose for an adult weighing about 140 pounds (63.6 Kg). The injection should be given deeply into the gluteus medius to avoid sloughing. In the hope of avoiding the pain of intramuscular injection, the intravenous route has been employed in a few cases. A patient suffering terrific pain from a coronary thrombosis was given 5 cc of undiluted paraldehyde into the vein at the rate of about 1 cc in three seconds. The patient lost consciousness in about ten seconds. Coincident with the onset of anesthesia there was a slight amount of pharyngeal irritation accompanied by coughing and a strong smell of paraldehyde on the breath. After a few coughs the patient appeared completely relaxed and slept quietly for about an hour. On awakening the pain was much less severe and could be controlled adequately with morphine. Intravenous paraldehyde in doses of from 7 to 10 cc has been used to control the restlessness and headache of a hypertensive patient with evidence of extensive cerebrovascular pathologic symptoms. This patient was violently nauseated by morphine and was unable to retain the barbituric acid derivatives by mouth or rectum. Quiet sleep was induced on each of six successive nights by the intravenous administration of 7 cc of paraldehyde. The sleep would last several hours but could be greatly prolonged by the rectal injection of from 5 to 10 grams (0.32 to 0.65 Gm) of sodium amytal which was retained if given after consciousness had been lost. This patient began to show some degree of tolerance to paraldehyde after two or three injections. Tolerance to paraldehyde unquestionably develops and habit formation has been reported but these should not be problems if the drug is used only occasionally to control severe pain or convulsive states requiring rapid anesthesia. Although

unpleasant it requires no sterilizing and has a wide margin of safety, while being almost instantaneous in action when administered parenterally.

**Immunization with Scarlet Fever Toxoid**—For active immunization, Daniel found that a total of 1.6 cc of the scarlet fever toxoid prepared by Veldee, divided into 0.1, 0.5 and 1 cc of the toxoid at intervals of three weeks, gave maximal immunization with minimal reaction. The same amount divided into two monthly doses gave rather marked reactions. In twenty-eight children less than 6 years of age there were no noticeable systemic reactions, locally there was a slight erythema but practically no induration. In the school group of 191 children, almost all had a reddened area from 1½ to 2 inches in diameter. In some of the cases there was a painful induration but in all cases smaller than the reddened area. The color in the erythematous areas was a deep red. There were only five systemic reactions, these consisted mainly of headache, fever, nausea and slight sore throat. In ten of the adult group of thirty-six cases rather marked reactions developed the reaction being in direct proportion to age. In general the average reaction was less than that for typhoid immunization, and, except for more local reaction, comparable to similar protection for diphtheria.

**Excretion of Estrin**—The experiments of Robson and his associates demonstrate that when ketohydroxyestrin is injected intramuscularly into the ovariectomized human female or subsequent to the menopause only a small proportion of the hormone can be recovered in an active form from the urine by the methods used. The result is confirmed by experiments in which urine was injected into ovariectomized mice without any previous treatment, for, although the toxicity of the urine rendered an accurate assay impossible yet it could be definitely established that the quantities were comparatively small. The results indicate that the human body can rapidly destroy or at any rate render inactive, the estrous hormone, and this view is supported by the finding that, four hours after the injection of 10,000 mouse units, the blood contained less than 25 mouse units of the hormone per liter.

\*Primary Cancer of the Lung: Its Incidence and Pathology R M Hill—p 320

**Primary Cancer of the Lung**—Hill analyzed most of the series of cases of primary cancer of the lung reported in the literature and found that pulmonary carcinoma forms about 1 per cent of all cases at necropsy and more than 8 per cent of all malignant diseases discovered after death. The increase in the incidence during recent years is probably largely relative. The disease occurs most commonly in the fifth and sixth decades of life, the average age being 51 years. The sexes are affected in the proportion of 77.87 per cent for men and 22.13 per cent for women. The etiology is not established clearly. The lungs are affected with almost equal frequency. There is no marked predilection for individual lobes. Bronchiectasis is a frequent sequel of carcinoma, and pleural effusion occurs in a third of the cases. Tumors composed largely of cells having a lesser degree of differentiation are slightly more common than the clearly defined carcinomas. The distribution of metastases is characterized by the frequency with which the suprarenals (15 per cent), kidneys (14 per cent) and brain (more than 10 per cent) are affected. The presence of cancer of the lung is often masked by bronchiectasis or pleural effusion. Emaciation is unusual. In a definite proportion of cases (about 15 per cent) there are no symptoms referable to the respiratory system. The period of survival is about six months, though the course may last several years.

## Glasgow Medical Journal

3 173 204 (May) 1934

Medical Education G H Edington—p 173

\*Sodium Citrate as a Hemostatic J B Hutchison—p 180

**Sodium Citrate as a Hemostatic**—Hutchison observed three patients in whom postoperative oozing of blood continued in spite of the administration of the usual hemostatics. In each of the cases bleeding ceased immediately following the intramuscular injection of 30 cc of a 30 per cent solution of sodium citrate. The effect of sodium citrate seems to be transitory. Its effect is noticed within a few minutes and is most marked in forty-five minutes when the coagulation time is found to have diminished from the normal seven or ten minutes, to about two minutes. It remains at this level for two or three hours and gradually returns to its original time. The pain of the injection

can be greatly reduced by the previous injection of 4 cc of 1 per cent solution of procaine hydrochloride into each buttock. It has a marked effect in jaundice cases, and when administered preoperatively greatly reduces hemorrhage both during and after the operation. The drug has no toxic action on the kidneys, but it destroys the platelets and thus frees substances that activate coagulation. Its use is contraindicated in diseases of the blood associated with destruction of platelets. Oral administration is slow and the effects are variable, subcutaneous injection causes pain and edema, while the intravenous route may give rise to severe shock if injection is too rapid.

**Hydrogen Ion Concentration of Venous Blood**—In determining the hydrogen ion concentration of whole blood without the addition of oxalate and fluoride, Harris and his associates have the room heated to 38 C and maintained at that temperature for one and one-half hours before use. At the end of this time the whole electrode system has attained blood temperature. The subject then enters the room and remains seated for five minutes before blood is withdrawn into a modified glass electrode of the Kerridge type. A reading is taken within two minutes of the blood leaving the vein, but not before equilibrium has been established. The authors believe that this method of temperature control and the avoidance of the loss of carbon dioxide is an advance on methods used heretofore in that the addition of oxalate and fluoride to the blood has been avoided. It is the only method which in their hands has yielded reliable results in a large series of cases. The results obtained from normal subjects come within the range of generally accepted normal values. In their cases, under normal resting conditions, the lowest  $p_H$  recorded was 7.27 and the highest 7.43 with an average of  $p_H$  7.36. They did not observe an acid change in any of their cases which corresponded to that described by Havard and Kerridge. This is in agreement with the observations of Platt and Dickinson, who believe that this so called acid change was due to faulty temperature control.

**Anaerobic Meningitis Following Mumps**—McEwan and Jackson present a case of anaerobic meningitis following mumps in which the isolated fusiform bacillus appeared to resemble the third type of Ghon, Mucha and Muller, and also the type II of Smith, although it showed no tendency to develop spiral forms on culture or darkground illumination as found by Smith and Tunnichiff in type II. Pathogenicity experiments were not carried out. The train of symptoms suggests that pus formation occurred first in or near the occipital bone. It is known that the organisms of the group occasionally invade bone either metastatically or directly, producing osteomyelitis with widespread necrosis. The external abscess was found to extend down to the bone. Slight signs of intracranial involvement appeared before any swelling was detectable externally, although there was stiffness and pain at the back of the neck. The aggravation of the intracranial symptoms and the development of the external swelling proceeded more or less concurrently. Pus formed on both aspects of the occipital bone, producing an external and an extradural abscess. The earlier specimens of cerebrospinal fluid were definitely purulent but sterile, and this is not uncommonly found with suppuration close to but not involving the meninges. Such an observation would be consistent with the presence of an extradural abscess. The final infection of the meninges indicates the rupture of this abscess internally. Necropsy was not obtained and clinical examination failed to show anything definitely suggestive. It is possible that the infection originated in the mouth, but there was no clinical enlargement or tenderness in the anterior group of cervical glands.

**Osteosynthesis of Fractured Neck of Femur**—Wright employed the following method of implanting the Smith-Petersen nail in fractures of the neck of the femur. With the femur abducted, inverted and extended, and with the shortening reduced, a vertical incision is made over the trochanter and through the iliotibial band. The nail is entered 15 cm below the great trochanteric ridge and aimed horizontally in a plane cutting the point of insertion and the opposite anterior superior iliac spine. An incision in the form of a couched S is used, the anterior limb lying ventral to the femur extending 2.5 cm (1 inch) distal to the trochanteric ridge. The anterior curve is 1.25 cm (half an inch) above the trochanteric ridge and curves down along the back of the trochanter to 1.25 cm below the trochanteric ridge. The dorsal limb curves cranially for from 2.5 to 5 cm (1 to 2 inches) on to and in the direction of the fibers of the aponeurosis of the gluteus maximus. Thus the scar is removed from pressure by the greater trochanter and lies in a natural fold of skin except anteriorly. The flap outlined by the anterior curve is reflected and gives access to the iliotibial tract covering the vastus lateralis. This is incised vertically and retracted to front and back, exposing the femur. An incision about 2.5 cm long is made, splitting the aponeurosis of the gluteus maximus medially and posteriorly to its insertion. A finger is passed through the incision in the gluteus maximus and the tendons of the obturator internus and externus are

identified. The neck of the femur is felt between these two, and by passing the finger medially along the lower border of the obturator internus tendon the dorso-inferior edge of the acetabulum is easily found and the necessary length of the nail can be measured on the finger, 1.25 cm being allowed for the head of the femur. With the finger and thumb of one hand on the anterior and posterior aspect of the neck, that at the posterior aspect being at the lower edge of the neck, the nail can be easily entered 15 cm below the trochanteric crest, pointing half way between the tips of the two digits in the horizontal axis and about 1 cm above the tip of the posterior digit in the coronal axis. It is then driven into the bone. About 3 mm (one-eighth inch) of the nail is left protruding. The fragments are impacted with a mallet and a cube of india rubber having a hole for the pin. The iliotibial band and gluteal aponeurosis are sutured and the skin margins are approximated. After the position of the pin has been confirmed by roentgen examination the patient is encouraged to move the limb on returning to bed. Weight bearing is allowed in about two weeks.

\*Effect of Spleen to Growth of Transplanted Tumor H Matsuoka  
—p 25

**Hydrogen Ion Concentration of the Umbilical Blood**—Mikawa studied the  $pH$  of the arterial and venous umbilical blood, the maternal venous blood and the retroplacental blood by means of his micromethod. He observed that the mean  $pH$  of the blood in the umbilical vein is  $7.326 \pm 0.011$ , while that in the umbilical arteries is  $7.288 \pm 0.006$ . In the asphyxiated new-born infant these two bloods become more acid, and the difference between the  $pH$  of the two becomes more marked than in the normal case. The retroplacental blood has a higher  $pH$  i.e. it is more alkaline, than the venous blood of the same parturient subject taken from the cubital vein immediately after parturition. Generally, the  $pH$  is  $7.344 \pm 0.008$  for the former and  $7.320 \pm 0.007$  for the latter, the latter being thus almost on the acid limit of the normal  $pH$  range for adults or for normal pregnant women. The arterial umbilical blood running along the umbilical vein had almost the same  $pH$  as the maternal venous blood.

**Effect of Spleen on Growth of Transplanted Tumor**—The experiments of Matsuoka with rabbit sarcoma and rat cancer indicated that the spleen had a relatively marked action to inhibit the growth of these transplanted tumors. This action not only was found round the spleen as an antagonistic factor to the tumor but, by affecting the whole body directly or indirectly inhibited the growth of the transplanted tumor in the sense that it disturbed the metabolism of carbohydrates, especially the glycolysis. The extirpation of the spleen invigorated the glycolytic power of the sarcomatous tissues. The antagonistic action of the spleen against the tumor was not so intense as not to admit the continual and nonmetastatic invasions of tumor tissues into the spleen.

 \*Blood Sugar Reducing Effect of Methylene Blue in Normal Subjects and in Diabetic Patients S Gabrielli—p 406  
 Recklinghausen's Disease with Multiple Osseous Lesions P Merklen and L Israel—p 411

**Blood Sugar Reducing Effect of Methylene Blue**—Gabrielli administered 50 Gm of dextrose by mouth together with 20 cc of a 1 per cent solution of methylene blue to normal subjects on a fasting stomach. The glycemic curve gradually sank during a half hour after administration but rose to the maximum at the end of the first hour. Another 20 cc of the solution of methylene blue was injected intravenously after an hour. This caused a drop in the glycemia. The minimal glycemic rate is reached by the third hour (0.4 Gm per thousand), after which the curve rises again to the glycemic rate at fasting time. Methylene blue has a marked blood sugar reducing action; it lowers the alimentary glycemic curve, the value of which is from 40 to 50 per cent below that of control tests. In several patients who had diabetes the top of the curve exceeded 50 per cent as calculated at fasting. While the curve was not modified by the methylene blue, it rose to 75 per cent above the initial glycemic rate. The second injection interrupted this ascending phase; the values remained unchanged for about an hour, after which the curve dropped to a deficient glycemic condition. Thus the methylene blue determined a marked lowering of the entire alimentary curve. Another diabetic patient on a fasting stomach presented a glycemic rate of 1.90 per thousand and poor tolerance to alimentary dextrose. The first administration of dextrose and methylene blue raised the top of the curve slightly and the second produced a rapid decline in the rate of glycemia. By the fourth hour the rate was back to that on a fasting stomach. Thus, methylene blue is able to diminish the glycemia of diabetic patients by approximately 20 per cent for a period of more than four hours. The blood sugar reducing effect of methylene blue is in relation to the amount of the solution injected. In order to obtain favorable results, it is necessary to introduce about 3 mg of methylene blue for each kilogram of body weight. All subjects and patients tolerated the injections well and no subjective symptoms were observed. The blood sugar reducing effect of methylene blue is probably in relation to the processes of oxydoreduction, which are characteristic of the substance. It would be interesting to verify whether methylene blue, which may accelerate oxydation of dextrose, has the power to modify acidotic conditions and different forms of diabetic coma due to these acidotic causes. The author feels that methylene blue merits further investigation.

**Treatment of Hydrocele**—Blavier treated eighteen patients having hydrocele by aspiration of the fluid and reinjection of a solution of double chlorhydrilactate of quinine and urea, 25 parts to 100 of glycerin (Vendel's solution). Cure resulted in all cases. The patients ranged in age from 32 to 73 years, and the duration of the hydrocele was from a few months to many years. It was noted that, although the sac usually refilled after the first and sometimes after subsequent injections the fluid was more viscous and more brown than the original. The reformed fluid tended to be smaller in quantity and to diminish gradually in the course of time. The injections were entirely painless. They lead to sclerosis of the wall of the hydrocele followed by total resorption of the fluid. They are without danger, since injections outside the sac cause little trouble. From the practical standpoint the author recommends a single dose of 3 cc of the solution in cases in which the volume of hydrocele fluid does not exceed 75 cc. If the volume is greater, 6 cc may be injected at once without danger. Usually it is useless to repeat the injection, since one is generally sufficient to effect a cure.

 \*New Clinical Sign of Folliculin Activity Test of Breasts G Sauphar—p 496

**Congestion of Breasts as Sign of Folliculin Activity**—Sauphar states that congestion of the breasts occurs almost constantly after the injection of a known dose of folliculin. It lasts a limited time and disappears without other symptoms, having provided a striking sign of the activity of the preparation employed. He observed that the results were more constant when an ester salt of folliculin, such as the benzoate, was used in place of the crystallized folliculin. In the second part of his work a preparation of dihydrofolliculin was therefore substituted for crystallized folliculin. The author believes that the benzoate of folliculin in single injection is the most active preparation, dihydrofolliculin administered orally in divided doses and crystallized folliculin orally give more inconstant results. Eight cases are reported showing this congestion of the breasts subsequent to the administration of folliculin preparation. The author states that in forty such patients only one negative result occurred. The best results are obtained with early administration of the folliculin, since resistance apparently occurs with the passage of time. Finally he states that congestion of the breasts is a single clinical phenomenon from which no conclusions can be drawn other than the activity of the preparation introduced. The positive breast sign probably indicates dosage considerably in excess of that necessary therapeutically.

**Influence of Calcium on Platelet Content of Blood**—Savagnone studied the quantitative modifications of the blood platelets during calcium therapy to determine whether calcium stimulates the production of fibrinogen in the blood. He administered intravenously 10 cc of calcium gluconate daily to ten patients who had pulmonary tuberculosis. One hour after injection there was a marked increase in the number of blood platelets. This increase was temporary and within from five to six hours the number of platelets was reduced again to its normal rate. After one month of intensive intravenous treatment no permanent variations were found in any of the patients. These results agree with those of a previous investigation made by the author, in which the calcium did not permanently influence the mechanism of coagulation.

**Intercostal Neuralgia in Gastric Ulcer**—Giordano and Nicastro report a case of painful syndrome constituted by intercostal neuralgia, with repercussion either vertebral (rachialgia) or epigastric, caused by ulcer of the lesser curvature of the stomach in a patient aged 53. The physical symptoms indicated the presence of gastric ulcer while the roentgen signs indicated only rigidity of the lesser curvature. At laparotomy an enormous ulcer of the lesser curvature was discovered. A gastrectomy, according to Poylas technic was performed. In order to interpret the syndrome the authors make a study of the innervation of the stomach. They say that the branches from the great sympathetic and pneumogastric nerves form in

the stomach two plexuses, one muscular and the other sub-mucous, with motor and sensory nervous endings, respectively. The centrifugal fibers of the stomach are divided into two groups: one ascending along the vagus and phrenic nerves and the sympathetic fibers of the aortic plexus, and the other lateral, which at the level of the sixth to the ninth segments of the spinal cord connects with spinal routes carrying somatic sensibility. This fact explains the change of the visceral pain into somatic pain at that level and, since the cutaneous parietal innervation of the intercostal spaces derives from afferent routes of the sympathetic, explains the neuralgia in the authors' case. The ascending fibers of the vagus and phrenic nerves produce a cutaneous innervation corresponding to the cervical segments of the spinal cord, causing areas of hyperalgesia at the level of the face, the neck and the back, which may also explain the vertebral repercussion of the pain in the authors' case.

Pseudo Anemia During Pregnancy W. Schultz —p. 110

**Sequels in Children Born During Tribrom-Ethanol Anesthesia**—Wahl shows that, following delivery during tribrom ethanol anesthesia, the new born occasionally show grave disturbances. In some cases there develop without prodromal symptoms, but immediately after birth, asphyctic conditions, which in spite of numerous therapeutic measures gradually subside only after more than an hour. Nearly 50 per cent of the children who have been delivered during tribrom-ethanol anesthesia are apathic for from two to four days after birth. There is weak whimpering instead of crying, poor and awkward nursing, increased aspiration of fluids and an abnormal weight curve. Consequently, considered from the standpoint of the welfare of the child, birth during tribrom-ethanol anesthesia is not to be recommended, and it is necessary to search for better methods.

**Lymphosarcomatosis of Female Genitalia**—Walther discusses six cases of lymphosarcomatosis of the female genitalia, two of which he himself observed. In five cases the tumor originated in the uterus, whereas in the other case it probably originated in the ovaries. Five tumors showed an average degree of maturity, that is, the tumor cells resembled lymphoblasts and lymphocytes, but in the sixth case the cellular polymorphism of the tumor tissues resembled the histologic structure of a retiothelial sarcoma. Here the lymphatic tissue of the tumors was extremely immature. The growth of the tumor tissues from the uterus and the ovaries led first, by way of infiltration, to an involvement of the neighboring genital organs. Then developed lymphogenous metastases in the retroperitoneal lymph nodes and in the more distant groups of lymph nodes and here and there also hematogenous metastases and implantation metastases. Spleen, liver and bone marrow never showed leukemic changes and in the case in which the blood was examined, leukemic changes were likewise absent. A systemic leukemic disorder can thus be excluded. The starting point of the lymphosarcoma was preexisting lymphatic tissue. In the first five cases it was lymphatic tissue of the uterine mucosa, in which the occurrence of lymph follicles is a frequent occurrence. If the starting point of the tumor formation is in the ovaries it is probable that a lymph follicle formation on an inflammatory basis was the matrix of the tumor. The clinical picture of lymphosarcomatosis of the uterus largely resembles that of carcinoma of the uterus, except that it is much more malignant, spreads more rapidly, metastasizes earlier and sooner leads to a fatal outcome than is the case in carcinoma of the uterus. Observations indicate that lymphosarcoma of the genitalia occurs in women between the ages of 45 and 65.

#### Vaccine Therapy in Brucella Melitensis Infection

Bianchi points out that widely differing therapeutic methods have been recommended for the treatment of Brucella melitensis infections. He mentions arsphenamine, acriflavine hydrochloride, colloidal metals, nonspecific protein therapy, hemotherapy, serum therapy and vaccine therapy. However, not one of these treatments has proved sufficiently successful to become generally accepted. Vaccine therapy has been tried with different types of vaccines, but the application was generally by subcutaneous or intramuscular injection, rarely by intravenous injection. Moved by Veratti's suggestion, the author commenced with systematic intravenous injections of vaccine in 1927. For the preparation of the vaccine he has followed the technique of Pfeiffer and Kolle, and he has always employed a laboratory strain derived from a human Brucella melitensis infection of several years ago. From a twenty-four hour culture, developed on ordinary or, still better, on liver agar, he prepares a suspension with an 0.85 per cent solution of sodium chloride and an addition of 0.5 per cent phenol. This suspension is sterilized by placing it for one hour in a water bath of 60°C. After that it is kept in the icebox and is renewed every four or five weeks. One loop of this stock suspension contains approximately two billion organisms. Dilutes of 1:10 are made with physiologic solution of sodium chloride and with an addition of 0.5 per cent phenol. Thus the tubes contain 1:10, 1:100 and 1:1,000, loop to 1 cc. They are likewise kept on ice and, if not used, they are renewed after about one month. The intravenous injection of a 1:1,000 dilution is usually followed from three to five hours later by a rather high fever reaction. Then, in the course of a profuse perspiration, the temperature gradually drops so as to reach after eight or ten hours the level it had before the injection. It is best to give the injection in the morning. The second injection is made from three to four days after the first, either with the double dose, or, if the fever after the first reaction exceeded 40°C (104°F), with 1.5 times the first dose. In many cases the patient's temperature began to decrease after the second injection and in some even after the first injection, but this should not be a temptation to discontinue the treatment, for a relapse may occur. The author advises four or five additional injections with constantly increasing doses in order to produce each time a fever reaction of the same intensity. Once the fever has disappeared, the intervals between injections should be lengthened from six to eight days. The author effected rapid and complete cure in twenty cases of Brucella melitensis infection. He cites others who obtained the same favorable results and concludes that the intravenous vaccine therapy is the most effective one in Brucella melitensis infections.

#### Gallbladder as Regulator of Enterohepatic Circulation

—Heckmann discusses the part played by the enterohepatic circulation in digestion and in detoxication and the function of

the gallbladder in the enterohepatic circulation. He concludes that with the exception of cholesterol and lecithin all biliary substances take part in the enterohepatic circulation. This signifies that the cells of the liver have to replace only those quantities of bile that are lost (elimination with the feces and so on), whereas the largest portion of the biliary constituents are carried to the liver with the portal blood and merely have to be excreted into the bile passages. In case of destruction of this circulation for instance by drainage or by Eck's fistula, there is a considerable reduction in the biliary secretion. Such a change in the enterohepatic circulation takes place also in diseases of the liver, such as cirrhosis, in which, as the result of the overflow of the enterohepatic circulation, large amounts of substances contained therein (urobilinogen and so on) enter into the greater circulation. The enterohepatic circulation acts as a protecting device in that it intercepts and isolates foreign compounds. These compounds experience the same fate as the sodium tetraiodophenolphthalein that is used for contrast filling in cholecystography. The gallbladder has the capacity to store and concentrate all the circulating bile. It acts as a regulator of the constantly circulating bile (from the liver to the intestine and back again to the liver) and its function is to adapt the circulating bile to the requirements of the digestion. Observations during cholecystography corroborate this and connections between disorders of the gallbladder and digestive disturbances, on the one hand, and functional disturbances of the liver, on the other hand, appear understandable. Toxins that enter the organism and are eliminated through the liver become concentrated in the gallbladder. Thus the gallbladder becomes a protective device of the entire organism, but particularly of the liver, however, it itself becomes especially exposed to the poison. The author points out that the exclusion of this protective organ favors the development of hepatic disorders. He stresses that the treatment of intoxications should avoid disturbing this protective device by avoiding antidotes that produce a contraction of the gallbladder.

Endoscopy of Rectum and Sigmoid with New Method of Unfolding Organ J. Goldberger—p 738

**Modification of Threshold of Temperature Perception**—Thinking that the determination of the threshold for temperature perception has not been sufficiently utilized clinically, Isler and Schneyer decided to find out whether the various forms of physical therapy change the threshold for temperature perception. They made 217 tests with many types of treatment, such as unilateral hot baths of the forearm, local application of hot air, the light cabinet, cold baths of the forearm, carbon dioxide baths, galvanic current, faradic current, high frequency apparatus, short waves, ultraviolet rays, diathermy, and histamine iontophoresis. They describe the results obtained with each of these treatments and in summarizing their observations they distinguish three groups. 1. Persons who had been subjected to treatment with the high frequency apparatus, the short wave tube apparatus, the faradic or galvanic current, the quartz lamp, histamine iontophoresis and epinephrine iontophoresis generally showed a reduction of the threshold for heat perception, and in many instances also an elevation of the threshold for the perception of cold. In these methods of treatment with the exception of the faradic current, the change of the threshold of stimulation was noticeable also on the side that had not been treated. 2. In persons in whom the various forms of hot applications (hot baths, hot air and light) usually resulted in an elevation of the threshold for heat and cold the change usually being limited to the side that had been treated. The cold baths of one forearm likewise heightened the threshold for the perception of both qualities of temperature. However, in contradistinction to the hot baths, the change was noticeable

on both sides. 3. In persons in whom the changes varied after diathermy, carbon dioxide baths or spark gap short waves, an increase of the threshold was about as frequent as a decrease. Thus the experiments proved that the majority of persons react uniformly to many forms of physical therapy. The fact that not all persons react in the same manner may be due to individual characteristics or to disease. On the basis of observations on normal persons, the authors are inclined to assume the first possibility.

**Reducing in Atypical Forms of Thyrosexual Insufficiency**—Stark is convinced that the obesities caused only by insufficiency of the thyroid or by dysfunction of the ovaries are rare. He calls attention to the so called thyrosexual insufficiency described by Borchardt, which is the result of the simultaneous dysfunction of the thyroid and the gonads. The main symptoms are fatigue, aversion to exertion, falling out of the hair and frequently cessation of menstruation. The author has the impression that most of the cases of endocrine obesity that came under his observation were atypical forms of thyrosexual insufficiency. Since the two endocrine components (thyroid and ovarian) are involved in varying intensity, the symptomatology is not quite as typical as that described by Borchardt. The diagnosis should aim to determine the predominance of one or the other endocrine factor, and the author thinks that the treatment can do this. He admits that this is not always easy, since nearly all forms of obesity react to thyroid preparations. However, if the efficacy of the thyroid preparations can be improved by ovarian preparations, a strong ovarian component may be assumed. The reaction of the patient to measures of dehydration likewise is a valuable aid in the diagnosis, in that it may reveal the presence of a myxedema like water retention and thus indicate a predominating thyroid component. The polyglandular genesis of the atypical forms of thyrosexual obesity makes it necessary that the treatment should aim not only to reduce the weight but also to stimulate the insufficient glandular action.

\*Mechanotherapy of Inflammatory Swelling of Liver F. Stolle—p 833  
New Intravenous Method in Obstetrics with Aid of Injection Apparatus and an Arm Support G. von Bud—p 833

**Glycerin Therapy of Renal and Ureteral Calculi**—Lickint points out that the great increase in the incidence of renal and ureteral calculi has augmented the demand for conservative remedies. After evaluating ureteral massage, dilation of the ureters, increased flooding of the urinary passages by the administration of large amounts of fluid, hypophyseal preparations for the stimulation of peristalsis, and the use of volatile oils, the author discusses the part of glycerin in normal metabolism, the elimination of glycerin following its administration and its mode of action in expelling calculi. He calls attention to its spasmolytic action, its stimulating effect on the peristalsis by withdrawal of water or by reflex action from the intestine to the ureters, its diuretic action, its lubricating action, the increased density and viscosity of the urine, and the facilitation of expulsion by dissolving and diminishing the calculi. The author points out that small doses will result in failure, and he advises the giving of 50 cc of glycerin three times daily for three successive days. He never observed undesirable effects after the administration of glycerin. He obtained expulsion of the stone in fourteen out of sixteen patients to whom he gave the dose mentioned.

**Treatment of Puerperal Hemorrhages**—Siedentopf points out that the treatment of postoperative hemorrhages should be as much as possible consider the causes of the puerperal hemorrhages but that this is often difficult. Profuse and sudden hemorrhages generally indicate the presence of a placental remnant, but other factors may likewise cause severe hemorrhages. Exploration and curettage would reveal the cause, but this measure is already a decisive step in the choice between

the active and conservative treatment and is therefore unsuitable as a purely diagnostic aid. Consequently it is generally necessary to decide on a definite therapeutic method without exact knowledge of the cause. Some gynecologists prefer the conservative method, while others advise active measures not only on the basis of anatomic considerations but also because the duration of the treatment can often be reduced. To evaluate the two methods, the author compared the results in 110 cases of conservative treatment with those in fifty-five cases of active treatment. The conservative therapy proved successful in seventy-seven cases and the active therapy in twenty-seven. He relates one case in which the active treatment effected rapid improvement. If the woman can be kept in fairly good general condition for several weeks, the conservative treatment may be considered successful, for approximately eight weeks after the delivery an intra-uterine intervention has lost its danger, and curettage can then be resorted to in order to effect a complete arrest of the treatment. The conservative therapy is a complete failure only if an active method becomes necessary before the dangerous period is over. The author gives a tabular report of the 165 cases. This table shows that of the 110 women who underwent conservative treatment only one died as the result of sepsis, while of the fifty-five who were actively treated five died of sepsis. Fever was more frequent in the actively treated cases (thirteen compared to seven). He concludes that his preference for the conservative treatment of puerperal hemorrhages is justified.

**Mechanotherapy of Inflammatory Swelling of Liver**—Stolle relates that in two patients with inflammatory swelling of the liver he obtained prompt reduction of the extreme pain by the use of elastic traction. He applied a strip of elastic adhesive bandage, 8 cm wide, so that, beginning in the median line of the back, it reached in the back approximately 2 cm below the border of the liver, and then, while the liver was being lifted, the bandage was brought with slight traction to the front and over the median line. A second strip covering one third of the width of the first one strengthened and secured the compressing and lifting action. Immediately following application of this bandage, the patients felt relieved. Because of the reduction in the swelling of the liver, the bandage became somewhat slack and was twice replaced by a new one. Each time the patients felt relieved. This mechanical treatment was supported by a suitable dietary therapy, which supplied comparatively large amounts of carbohydrates, particularly dextrose, and curtailed the intake of proteins, and by medicinal treatment in the form of magnesium sulphate, medical charcoal and occasionally methenamine.

- Therapy of Nutritive Allergic Disorders K P Eiselberg and F Kauders—p 679
- \*Roentgen Therapy of Hyperthyroidism P Petras—p 681

**Increase in Sugar in Blood Following Thoracoplasty**—Scharff reviews the literature and relates his observations made on thirteen patients after fifteen interventions. With the exception of two cases, all the operations were done under local anesthesia. The sugar content of the blood was determined before and after the operation, and a postoperative increase was observed in all instances. At the peak of the hyperglycemia, a temporary glycosuria was noted frequently. Acetone and aceto-acetic acid were not demonstrable in the urine. Severe disturbances such as decompensated acidosis, were absent but there was a parallelism between the metabolic disorders and the general condition.

**Roentgen Therapy of Hyperthyroidism**—Petras employed roentgen rays in the treatment of forty-two cases of hyperthyroidism. He uses rays of medium hardness which are filtered through 0.5 mm of zinc and 1 mm of aluminum. The tension is 160 kilovolts. The therapy is applied in series of three treatments. The intervals between the treatments last eight days and between the series from six weeks to several months. It is advisable to commence the first series with small

doses of from 60 to 90 roentgens at each session. During the second series, from 120 to 180 roentgens may be administered at each session. The author observed favorable effects in two thirds of the cases. He admits that the result is not as prompt as after surgical treatment but points out that the irradiation avoids the operative mortality, which averages from 2 to 8 per cent. During roentgen therapy the symptoms disappear more gradually. The improvement becomes noticeable particularly in the disappearance of the nervous symptoms. Tremor and insomnia disappear, the appetite improves, and the diarrhea ceases. There is also improvement in the cardiovascular syndrome, but its complete disappearance requires considerable time. The ocular symptoms are still more refractory, for many patients who have regained their working capacity still have a considerable exophthalmos and Graefe's sign. The weight of the patients increases considerably, but the basal metabolic rate decreases slowly. The author concludes that roentgen therapy of exophthalmic goiter deserves a place beside the surgical treatment.

**Copper-Iron Therapy in Anemia of Adults**—Machold relates his experiences with an iron-copper preparation. It was administered in the form of candies, each of which contained 0.1 Gm of ferrous chloride, 2.5 mg of copper in the form of lactate of copper and liver and stomach extract as base. The average daily dose was ten candies, so that the patient received daily 1 Gm of iron, 25 mg of copper and about 1 Gm of liver and stomach extract. The author is convinced that the efficacy of the preparation is not due to this small amount of liver and stomach extracts, but he ascribes it to the iron and copper content. He employed the candies in the treatment of posthemorrhagic anemias and found that the combined iron and copper therapy is superior to the ordinary iron therapy and that its stimulating effect on the bone marrow is superior to that of liver therapy. In anemia of infectious origin, in which the erythropoiesis was impaired, the stimulating effect of the copper and iron therapy again proved superior to that of liver therapy. Toxic impairment of the erythropoiesis responded better to the copper-iron therapy than to treatment with liver and arsenic. In hypochromic anemia after intestinal tuberculosis the combined copper-iron therapy proved as effective as a tenfold iron dose. In fact, the copper-iron therapy proved superior in all forms of anemia generally designated as secondary. The observations in cases of pernicious anemia are not sufficiently numerous to justify a definite evaluation, but promising results of the copper-iron therapy were noted in some instances, particularly in those not yet too far advanced.

**Renal Insufficiency in Nephritis**—Kutschera-Aichberger distinguishes two forms of nephritis, the intra-infectious and the postinfectious. The first form is due to a direct bacterial impairment of the renal tissues, while circulatory disturbances predominate in the second form. In intra-infectious nephritis there is never an acute renal insufficiency during the acute stage and during the chronic stage only when most of the glomeruli are closed by finely granular emboli. In post-infectious nephritis (hypertension nephritis), insufficiency may develop during the acute as well as the chronic stage. The characteristic sign of hypertension nephritis is the reduction of the water elimination. This disturbance is not so much the

result of inflammation as of an insufficient blood perfusion of the glomeruli. In chronic hypertension nephritis, two different forms of renal insufficiency should be differentiated: (1) cases in which there are severe morphologic changes, (2) cases in which there are relatively slight lesions of the renal parenchyma. In the latter group a functional factor is responsible, especially a disturbance of the renal circulation. There is a causal connection between the functional and the organic changes of hypertension nephritis, and the therapy should therefore make efforts to overcome the functional circulatory disturbances, as long as the organic changes have not progressed too far. A comparison of the different manifestations of insufficiency with the morphologic changes in the various renal elements permits the following conclusions about the physiology of the human kidney, which corroborate and supplement Volhard's theory: 1. The water elimination takes place primarily through the glomeruli. If they do not function their activity may be taken over although insufficiently, by the main portion of the uriniferous tubules. 2. The concentration of the urine is due to the secretory function of the epithelium of the main portions of the tubules. In addition to this, a reabsorption of water by Henle's loops has to be considered.

Torsion of Hydatid of Morgagni (Parovarian Cyst) I. Caesar—p. 1282

**Anuria and Oliguria in Eclampsia**—Spickmann maintains that oliguria is a frequent occurrence in the course of eclampsia. It is usually accompanied by a temporary decrease in the blood pressure but, as soon as the diuresis improves, the blood pressure increases and then returns to the normal level in a few days. Oliguria is especially frequent immediately after delivery. The prognosis is favorable. Complete anuria occurs less often during the puerperium. In mild cases of short duration, the anuria is likewise accompanied by a temporary decrease in blood pressure but in the majority of cases the blood pressure increases noticeably with the onset of anuria and remains constantly increased. In other cases again, the anuria is accompanied by an especially low blood pressure, which indicates progressive cardiac insufficiency. Generally the anuria begins later during the puerperium than does the oliguria. The prognosis of anuria is unfavorable. The author states that some cases of oliguria react to diuretics of the group of purine bodies with increased diuresis. However, this increase in the diuresis cannot be interpreted as indicating a favorable outcome. Diuretics fail in severe cases of anuria. Moreover, some diuretics of the group of purine bodies involve a certain danger, since their stimulating effect on the central nervous system may provoke eclamptic attacks.

**Micromethod in Determining Erythrocyte Sedimentation Speed**—Deinum uses a capillary tube 12 cm in length and 1.5 mm in diameter, in which he aspirates 2 cc of a 4.5 per cent solution of sodium citrate. A drop of blood from the finger is sucked in the tube until the column is 10 cm long. The tube is first held perpendicularly and then at a slant. As soon as the column reaches mark 10 the contents are poured out in a watch glass and the blood and citrate are thoroughly mixed. After this the tube is filled up again to mark 5 and one end of the tube is sealed with petrolatum or with a small flame. The tube is placed in a holder; it must

be held vertical, since the slightest inclination diminishes the sedimentation speed. The tube is left standing so that the erythrocytes may settle. After an hour the length of the clear column above the settled erythrocytes is read by means of a ruler made of a strip of millimeter paper. The average value attained by this method in normal children is 6 mm, although 8 mm is still considered normal. The capillary method gives higher results than the methods of Eldahl and Langer for greater sedimentation speed. The method was used especially in cases of tuberculosis. In children in whom the temperature had disappeared and in whom the general examination was satisfactory there was at the same time a decline in the erythrocyte sedimentation speed. If the speed has not diminished, this constitutes a warning to distrust the apparent improvement. In a patient presenting rectal hyperthermia with a temperature of 98.6° F. as the only symptom, the normal value of 6 mm of the erythrocyte sedimentation speed confirmed the diagnosis. The author states in conclusion that this method is to be recommended for its simplicity and reliability.

## ONE DOSE ALUM TOXOID IN DIPHTHERIA IMMUNIZATION

CHAIRMAN'S ADDRESS

ALFRED A WALKER, M.D.  
BIRMINGHAM, ALA

Immunization against diphtheria has in recent years received more attention from pediatricians and health workers than any other phase of preventive medicine. Within the last year there has come into general use a new method which, because it has the great advantage of requiring only one injection, promises to displace all other methods of accomplishing such immunization. Much has been written by laboratory and health workers on the use of a single dose of alum toxoid, but little if any of this has appeared in the pediatric literature, and yet it is the practicing physician and especially the pediatrician who in the final analysis is most interested. It is for this reason, and in the hope of stimulating enough interest to secure the necessary clinical evaluation, that I take this opportunity for discussing the new method.

Since the days of von Behring, who first neutralized diphtheria toxin with antitoxin in order to immunize animals safely and then applied this method to man, there has been an unbroken sequence of developments to improve and perfect the technic of the immunizing process. The ideal method of artificial immunization against an infectious disease should meet four specifications: (1) The number of treatments should be reduced to a minimum, (2) the period for the development of immunity should approximate that of the incubation period of the disease, (3) the injection should be safe with little or no disagreeable reaction, and (4) the method should be as nearly perfect as possible in effecting lasting immunity. The vast amount of work that has gone before has adhered always to this ideal.

The central fact in all immunizations against diphtheria is that it is the toxin that immunizes, but to be effective its toxicity must be reduced or so modified that it can be given without danger. The old toxin-antitoxin, which contained relatively large amounts of toxin (3 L +), neutralized with three and one-half units of antitoxin, proved to be unsatisfactory chiefly because its use was followed by frequent severe local and general reactions. To overcome this difficulty, Park and Zingher experimented with preparations containing less toxin and finally devised a mixture containing 0.1 L + of toxin and 0.75 unit of antitoxin. With this mixture the reactions were very much less severe than with the older preparations and the immunity obtained just as satisfactory.

It has long been observed that diphtheria toxin deteriorates with time, it loses both toxicity and the power to neutralize antitoxin. Fortunately, however, toxicity is lost much faster than combining power. The discovery of this fact led to the idea of modifying diphtheria toxin by physical means in such a manner that its toxic effects are reduced while a relatively large amount of the specific antigen is retained. Working along these lines, Glenny and associates in England found that the addition of 0.1 per cent formaldehyde to toxin rendered it nontoxic without material loss of its antigenic properties. Then in this country Park and his co-workers, promptly grasping the importance of this, injected a large group of school children with a toxoid that was made by adding 0.1 per cent of formaldehyde and then incubating at 37 C for five weeks. Much of the work that followed was based on these experiments.

In the meantime it has been noted by many workers that the small amount of horse serum present in the old toxin-antitoxin mixture occasionally resulted in sensitization to horse serum, and in order to obviate this danger an antitoxin prepared with goat serum was used for neutralization of the toxin. While these preparations were effective in from 70 to 75 per cent of cases, it was realized that it would be a distinct advantage to use a preparation that contained no foreign proteins in the form of animal serum, and this stimulated the search for a preparation that could be detoxified by a combination of chemical and physical means. Larson developed a toxoid that had been detoxified by the addition of sodium ricinoleate, and for a time this preparation seemed in certain parts of the country to give satisfactory results. For one reason or another, however, Larson's mixture never came into general use, and the search has continued.

While all these agents were fairly satisfactory in producing a negative Schick test, each had its disadvantage. The old toxin-antitoxin was unstable and under certain conditions could become highly toxic. In addition, in order to accomplish the best results, it was necessary to give three injections. The desirability of reducing the number of injections to a minimum and at the same time of increasing the antigenic response led to the production of a toxoid of high antigenic potency detoxified by aging with the addition of formaldehyde. This anatoxin or toxoid, which was developed by Ramon, was given in two injections at an interval of from two to four weeks. It was effective in producing immunity in about 80 per cent of the children in three months and in from 90 to 100 per cent in six months. This proved to be an important forward step, for the immunization was from 20 to 30 per cent more effective; no sensitizing serum was present, the preparation was more stable, and the reactions were not objectionable. Until approximately one year ago this was the preparation of choice.

Ramon, while endeavoring to improve the antigenic properties of his toxoid, observed in 1925 an increased antitoxin production in horses that developed abscesses at the site of injection. In the effort to slow down the rate of absorption he conceived the idea of adding tapioca to toxoid, whereupon he obtained a marked increase in antigenic stimulation. With the same object in view, Glenny and his associates used alum in various concentrations and found this to be very effective. Following this work, Park and his associates added 0.2 per cent of alum to their toxoid and proved that the immunity response in both guinea-pigs and children was markedly increased. They considered it necessary, however, to give at least 0.5 cc in three injections at weekly intervals, with which technic they obtained negative Schick tests in approximately 99 per cent of known positive reactors. This increased efficiency Park attributed to lessened solubility of the toxoid with correspondingly slow absorption.

A little later, Glenny and Barr<sup>1</sup> described the complete precipitation of toxoid by from 1.5 to 2 per cent solution of alum and found a marked increase in antitoxin formation in horses. Following this work they stated that it appeared possible by this method to produce a product that would in a single injection immunize human beings beyond the Schick level of immunity. Following this suggestion, Havens and his co-workers<sup>2</sup> of the Alabama State Health Department prepared a toxoid that was more or less completely precipitated by the addition of 2 per cent alum. It was found that between 75 and 80 per cent of the specific antigen remained in the precipitate thus prepared and that from 50 to 75 per cent of the extraneous nitrogenous products were eliminated in the filtrate. This precipitate was further purified by washing with salt solution, in which vehicle it was later suspended and standardized to contain ten plus flocculation units per cubic centimeter. When injected in guinea-pigs this agent, as was verified by Harrison<sup>3</sup> of the National Institute of Health, was found to be from twenty to fifty times more effective than soluble toxoid in producing antitoxin.

The developments in the field of immunology which I have just sketched were based largely on experiments with the lower animals. That which follows deals with the human subject, and notably with work done in Alabama. In the fall of 1931, following his earlier experiments, Havens gave to each of a group of children from 6 to 10 years of age, all strongly Schick positive, 1 cc of alum precipitated toxoid with from five to ten flocculation units. He found that the immunity response as measured by the Schick test was as good after this one dose as had heretofore been obtained from two or three injections of any other preparation. Since the results were slightly better with the higher unitage the standard of ten plus flocculation was adopted. This represents an epoch marking advance in diphtheria immunization.

The increase thus seen in the effectiveness of one dose is not difficult to explain. It lies apparently in the fact that precipitated toxoid is relatively insoluble and therefore is absorbed slowly. Slow absorption means that less antigen is lost by excretion and, as was shown to be true by Glenny, Buttle and Stevens,<sup>4</sup> that

it remains in the tissues long enough to act as its own secondary stimulus to antitoxin production. The application of this principle has been demonstrated also by Straus,<sup>5</sup> who incorporated a concentrated toxoid of high antigenic potency in hydrous wool fat and with a single dose obtained 99 per cent effectiveness in a small series of children.

Subsequently, further tests of this immunizing agent were made on larger groups of children by Graham, Murphree and Gill,<sup>6</sup> with equally good results. Confirmatory evidence was obtained by McGinnes in Virginia, who used the precipitated toxoid prepared in the laboratories of the Alabama State Health Department. In the spring of 1933 the National Institute of Health put its stamp of approval on this product, and its manufacture was started by the commercial biologic laboratories. Since that time many thousand children have received the alum precipitated toxoid according to the technic of Havens and numerous health departments throughout the country are now using it as their standard method of immunization. The advantages of using a preparation requiring only one injection are obvious, especially when used for mass immunizations.

Dr W. H. Park<sup>7</sup> introduced the use of alum precipitated toxoid in the public schools of New York City beginning in February 1934 and found that the one dose conferred immunity in from 90 to 95 per cent of susceptible children. In a later communication (April 7) he tells me that after nine weeks he obtained 87 per cent negative reactions in a series of sixty-nine children aged from 6 months to 3 years and that he is of the opinion that more than 95 per cent would react negatively a little later. In an address before a joint meeting of the Philadelphia Pediatric Society, the New England Pediatric Society and the Pediatric Section of the New York Academy of Medicine, Dr Park<sup>8</sup> stated that the effect of alum precipitated toxoid was more than double that of toxoid in fluid form and that it was rapidly displacing all other methods of immunization. Baker and Gill<sup>9</sup> reported the results obtained in more than 16,000 immunizations.

Untoward reactions are few. Park<sup>7</sup> states that he found practically no reactions in children under 2 years of age but that older children occasionally showed some disturbance, this was not sufficiently marked, however, to be seriously objectionable. Others have reported sterile abscess formation. Why this should occur, I am unable to say. On the whole, reactions are so rare and mild that they may be disregarded.

My personal experience with alum precipitated toxoid started in February 1933, when my colleagues and I received a supply of this material from the Alabama State Board of Health. It was used by us in our private practice in the age group from 6 to 18 months, which, as is well known, is the ideal age for the immunization and the age at which the immunity response is best. There were 135 infants in this series who were given 1 cc of alum precipitated toxoid without a preliminary Schick test. None of this group had a reaction other than an occasional slight induration.

All received the Schick test in from two to six months and all reacted negatively

In the Employees' Hospital of the Tennessee Coal and Iron Railroad Company, alum toxoid was given in one injection to 170 Schick positive children aged from 7 to 12 years. One hundred and sixty-five of these children were retested in four or five months and all reacted negatively. In another group of children who received no preliminary Schick test the result was a 100 per cent negative reaction in from two to five months. Of these 1,095 were infants under 1 year of age, of whom 770 were tested. In the age group

TABLE 1—Results Obtained with Alum Toxoid at the Tennessee Coal and Iron Railroad Company Employees Hospital Fairfield, Ala

	Age	Under 1 Year	1 to 6 Years	7 to 12 Years	Total
Susceptibles immunization					
Alum toxoid				160	
Schick negative (from four to five months later)				160	
No preliminary Schick tests given					
Alum toxoid		710	992	27	1729
Schick negative (from two to five months later)		770	992	27	1789

from 1 to 6 there were 1,353, of whom 992 were tested. There were twenty-nine in the age group from 7 to 12, of whom twenty-seven were tested. Although these results were comparable to those obtained by others, it was felt that the total lack of positive reactors might be in part due to a deficiency in the potency of the toxin used for the tests. In all instances the toxin used was a stable peptone preparation supplied by the state board of health, and when this question arose it was retested and was found to conform to all tests for potency. Further tests were made on nonimmune children, who gave satisfactorily positive reactions.

The department of preventive medicine and public health of Vanderbilt University School of Medicine was furnished with a supply of alum precipitated toxoid by the Alabama State Board of Health. Under

TABLE 2—Results Obtained with Alum Toxoid at the Vanderbilt School of Medicine Department of Preventive Medicine

	Per Cent Schick Negative After					
	14 Days	22 Days	28 Days	42 Days	60 Days	90 Days
Group 1 (23 Schick +)	60	95.6		100		
Group 2 (23 Schick +)		92.4			94.3	96.2
Group 3 (8 Schick +)			100			

the direction of Alvin E. Keller,<sup>10</sup> children from two institutions close to Nashville, Tenn., were each given a Schick test and the positive reactors were given 1 cc of the toxoid. In order to determine how soon immunity resulted, the children were given another Schick test at different intervals beginning two weeks after the injection. In one group of twenty-three Schick positive children, 60 per cent were negative in fourteen days. In the same group 95.6 per cent were negative in twenty-eight days and 100 per cent in forty-two days after the injection. In another group of fifty-three children, 92.4 per cent were Schick negative twenty-two days after receiving the injection. 94.3 per

cent were negative in sixty days, and 96.2 per cent were negative in ninety days. In another group of eight children, every one was negative one month after injection.

Keller states that the results following immunization with a single dose of alum precipitated toxoid compare favorably with those obtained with two doses of toxoid and are much better than those reported following three injections of standard diphtheria toxin-antitoxin.

In an effort to determine whether the immunity conferred by this method was a lasting one, Gill,<sup>11</sup> within the month, has retested forty of the original group who were each given the toxoid two years ago and found one who gave a slight positive reaction while the others were all negative. All these children were strongly Schick positive before receiving the toxoid and all had reacted negatively following the injection. It is suggested that further tests be made on larger groups in order to determine this question definitely.

Painstaking animal experiment and careful clinical observation throughout the years from von Behring's day to the present time have enhanced enormously the efficiency of efforts toward the production of artificial immunity against diphtheria. The culmination of all this is seen in the achievement of Havens and others, who, by means of a single injection of a newly devised toxoid mixture, have succeeded in producing immunity in a surpassingly high percentage of susceptible children.

## DIFFICULTY IN SWALLOWING IN ACUTE EPIDEMIC POLIOMYELITIS

M. BERNARD BRAHDY, MD

MOUNT VERNON, N. Y.

AND

MAURICE LENARSKY, MD

Associate Attending Physician and Resident Physician, Respectively  
Willard Parker Hospital, New York

NEW YORK

At the beginning of the paralytic stage of poliomyelitis, many patients with paralysis of the lower cranial nerves have difficulty in swallowing. This condition is seen more frequently in the hospital than in private practice. This may be because inability to swallow is an alarming symptom and, when it occurs, the parents request hospitalization for the patient. One of the questions we were frequently asked was whether the patient would be able to swallow again. Based on our experience in the past, we always gave a good prognosis. However, when some of the patients were unable to swallow week after week, we turned to the literature for information. The available data on the subject were very meager and for that reason we present our observations.

During the period from July 1 to Dec. 1, 1933, there were 123 patients with cranial nerve lesions due to poliomyelitis admitted to the Willard Parker Hospital. Among these 123 patients, difficulty in swallowing occurred in 87. The condition was observed in the hospital in eighty-one and noted in the history of six others. In most patients the difficulty in swallowing occurred before the fourth day of the illness, but in some it was not observed until the eighth day. The condition cleared up in the majority of our patients in

<sup>11</sup> Gill, D. G. Personal communication to the author from the Willard Parker Hospital and the Department of Pediatrics, Cornell University Medical College.

a week. However, there were five patients who were of particular interest, because they were unable to swallow for twenty-one, twenty-five, thirty-five, fifty-one and seventy-one days, respectively, and they will be considered in detail later.

## SEX AND AGE

In the entire group of 123 patients with bulbar lesions there were seventy-nine males and forty-four females. Of these, fifty-nine males (75 per cent) and

TABLE 1—Percentage of Bulbar Cases with Difficulty in Swallowing, According to Age

33	1	1	100
38	1	1	100

twenty-eight females (64 per cent) had difficulty in swallowing, indicating a slightly higher rate of incidence among the males who had bulbar lesions.

The youngest patient was 2 years of age and the oldest 38. The average age was 9 years. It was interesting to note that the older the patient with cranial nerve lesions, the more likely he was to have difficulty in swallowing. This tendency is shown in table 1, in which the number and percentage of bulbar cases with difficulty in swallowing is given according to the ages of the patients.

TABLE 2—Duration of Difficulty in Swallowing

Days	Number of Patients	Days	Number of Patients

## TIME FACTORS

Most of the patients were again able to swallow practically normally in a week (table 2). Ten patients continued to have difficulty in swallowing for from eight to seventeen days and five were unable to swallow for more than seventeen days. The average duration was seven days.

There was no correlation between the day of the illness that difficulty in swallowing began and its duration. Neither was there any correlation between the number of cranial nerves involved and the duration of the difficulty in swallowing.

## PHYSIOLOGY

A brief consideration of some of the important points of the physiology of deglutition will suffice to show that it is a rather complex performance.<sup>1</sup> Part of the act of deglutition is voluntary and part is involuntary. In general it is divided into three stages.

The first stage consists of the passage of the bolus of food between the anterior pillars of the fauces (isthmus of the fauces). This part of the act is usually ascribed to the movement of the tongue itself. The bolus of food lying on the upper surface of the tongue is forced backward by the elevation of the tongue against the soft palate.

The second stage comprises the passage of the bolus from the isthmus of the fauces to the esophagus, i. e., its transit through the pharynx. The mylohyoid muscle quickly contracts and the bolus of food put under pressure is shot into and through the pharynx. The contraction of the mylohyoid muscle marks the beginning of the second stage, the first event of which is that the bolus, by stimulating sensory nerve ends, acts on the nerve centers situated in the medulla oblongata, so as to cause a coordinated series of movements of the muscles of the pharynx and larynx and an inhibition for a moment of the respiratory center. The mouth cavity is shut off by the position of the tongue against the palate and by the contraction of the muscles of the anterior pillars of the fauces. The opening into the nasal cavity is closed by the elevation of the soft palate (action of the levator palati and tensor palati muscles) and by the contraction of the posterior pillars of the fauces (palatopharyngeal muscles) and the elevation of the uvula (azygos uvulae muscles). The soft palate, uvula and posterior pillars thus form a sloping surface, shutting off the nasal chamber and facilitating the passage of the food backward through the pharynx. The respiratory opening into the larynx is closed by the adduction of the vocal cords (lateral crico-arytenoids and constrictors of the glottis) and by the strong elevation of the entire larynx and a depression of the epiglottis over the larynx (actions of the thyrohyoids, digastrics, geniohyoids and mylohyoids and the muscles in the aryteno-epiglottidean folds).

The third stage is the passage of the food through the esophagus. When the food is solid or semisolid it is forced down the esophagus by a peristaltic movement of the musculature. The contraction of the esophageal muscles is the motor response of a reflex initiated in the mucous membrane of the pharynx and esophagus. The afferent nerves concerned in this reflex include branches of the glossopharyngeal (ninth), trigeminal (fifth) and vagus (tenth). The motor fibers concerned in the reflex comprise the hypoglossal (twelfth), trigeminal (fifth), glossopharyngeal (ninth), vagus (tenth) and the spinal accessory (eleventh) nerves.

The afferent fibers in the glossopharyngeal nerve exercise a powerful inhibitory influence on the center of deglutition as well as on that of respiration. When the glossopharyngeal nerves are cut the esophagus enters into a condition of tonic contraction, which may last a day or so.

When the act of deglutition depends on so many muscles and cranial nerves it is not surprising that difficulty in swallowing is experienced by many patients with the bulbar type of poliomyelitis.

<sup>1</sup> The description of the physiology of deglutition has been condensed from chapters on this subject in a Text Book of Physiology, by William H. Howell (Philadelphia: W. B. Saunders Company, 1919) and Physiology and Biochemistry in Modern Medicine, by J. J. R. Macleod (St. Louis: C. V. Mosby Company, 1928).

## CLINICAL CLASSIFICATION

Clinically the patients presented several different types of difficulty in swallowing. They fell more or less into four groups:

1. Regurgitation through the nose due to paralysis of the soft palate.

2. Accumulation of food in the throat associated with a sensation of fullness. The food was either regurgitated or swallowed very slowly. We thought this was due to paralysis of the pharyngeal muscles, but, after studying the physiology more carefully, we think it was probably a result of paralysis of the mylohyoid or other muscles associated with the second stage of deglutition.

3. Small amounts of food swallowed with difficulty and then vomited, which may have been due to pharyngeal or esophageal muscle paralysis.

4. Coughing when an attempt was made to swallow, being due to failure to close off the larynx, the result of paralysis either of the vocal cords or of the muscles that elevate the larynx (thyrohyoids, digastrics, geniohyoids and mylohyoids).

Those patients who choked or coughed when they attempted to swallow and those who were unable to swallow their saliva (group 4) received fluids subcutaneously, intravenously and rectally. After several days, gavage was tried. If the fluid was retained, either the gavage was repeated or the patient was fed through a Levin tube. We found the latter a most satisfactory way of feeding patients with prolonged inability to swallow. We did not use continuous venoclysis<sup>3</sup> but think it would be a helpful addition in the treatment. When necessary, postural drainage was instituted and secretions that accumulated in the pharynx were removed by suction. We have used postural drainage (foot end of bed elevated and patient's head turned to the side) in these cases with considerable success for several years.

It may be necessary to tilt the bed from 15 to 20 degrees. Murphy<sup>4</sup> experimented with curarized cats kept alive in a Drinker respirator. He found that, when the cats were tilted head down at an angle of 15 degrees with the horizontal, fluid dropped into the trachea was not aspirated into the lungs. Durand<sup>5</sup>

TABLE 3—Late Results in Five Patients with Prolonged Inability to Swallow

Patient Case Number	Sex	Age in Years	Type of Polio myelitis	Duration of Inability to Swallowing	Follow Up					
					Time in Months	Excessive Saliva and mucus	Voice	Swallowing	Comment	
M H 1	♂	33	Bulbar	51 days	4½	++	Husky nasal	Swallowed well but had to be done slowly at times	Slight left facial and palatal paralysis, diminished expansion of right chest with dullness and moist râles (the patient died of pulmonary tuberculosis 2 months after the follow up examination)	
H W 2	♂	3	Bulbar	71 days	3½	+	Husky speech indistinct	Normal	Movement of palate sluggish, few rhonchi and coarse moist râles	
D F 3	♂	19	Bulbar	30 days	5	Slight	Slightly husky	Normal	Slight asymmetry of palate, gained 20 pounds	
M B 4	♀	9	Bulbo spinal	27 days	6	+	Husky nasal	Normal	Paralysis of intercostal muscles and diaphragm, left facial and palatal paralysis	
P G 5	♀	8	Bulbo spinal	21 days	5½	Slight	Slightly husky	Normal	No residual paralysis	

Six patients were extremely drowsy or stuporous, owing to an associated encephalitis or toxemia. Which group, if any, these would fall into we were not able to determine.

Our clinical classification is admittedly crude, but the diagnostic criteria at our disposal precluded a more accurate localization of the lesions present.

## TREATMENT

The treatment that the patients received varied according to their clinical classification. Those who had nasal regurgitation (group 1) were fed semisolid food or, if necessary, a gavage was given. Approximately one third of the patients did not require gavage. For patients who regurgitated or vomited after attempting to swallow (groups 2 and 3), gavage was given, or, if the condition lasted several days, they were fed through a Levin tube.<sup>2</sup> This is a rubber tube about 45 inches long with a velvet eye at the terminal end similar to that in a urethral catheter. There is no metal bucket attachment. There are oval openings on the side at the terminal end. The tube comes in three sizes, 16, 14 and 10 French. The thickness of the rubber is the same as that of a urethral catheter. The tube was originally designed for obtaining specimens of gastric and duodenal contents for examination. Levin advised that the tube be passed through the nose.

suggested tying the patient's feet to the end of the bed to permit adequate tilting.

Difficulty in swallowing associated with choking or vomiting, when occurring in a patient with respiratory distress, is of especial importance. There is a marked tendency to aspiration of fluid (vomit or saliva) in patients with a diminished cough reflex due to respiratory embarrassment, and the tendency is increased by treatment in a respirator.<sup>6</sup> Feeding by mouth (including gavage) is contraindicated for these patients until they are able to take food without untoward results.

Sedatives (one of the barbitol compounds) were administered when necessary. No other medication was used.

## PROLONGED INABILITY TO SWALLOW

Based on our previous experience and that of all writers who have commented on the subject, we thought that the difficulty in swallowing due to poliomyelitis lasted for from a few days to a few weeks.

2. Levin A. L. A New Gastroduodenal Catheter. *J. A. M. A.* 76:1007 (April 9) 1921.

During the past three years 1,334 patients with poliomyelitis were admitted to the Willard Parker Hospital. As far as we can recall, no patient had difficulty in swallowing beyond the period of isolation, which is twenty-one days. This is to a great extent consistent with the response of bulbar lesions in general. The majority of them either progress rapidly to cause the death of the patient or improve in a short time. Durand<sup>5</sup> found that paralysis of the muscles of deglutition generally cleared up in from a few days to two weeks. Shambaugh, Harrison and Farrell<sup>7</sup> also noted that paralysis of deglutition cleared up quickly and completely in a short time. Peabody, Draper and Dochez<sup>8</sup> state that "while the situation (inability to swallow) appears at the time to be most serious, the tendency to recover seems to be much better than one would expect, and return of function may take place even after ten days of paralysis." In view of this unanimity of opinion we were greatly interested in the course of five patients who were unable to swallow for from three to ten weeks (table 3).

In three of the five patients, respiratory difficulty developed which was sufficiently severe to require treatment in a respirator. One of these three patients (patient 1) was in the respirator for eight hours during the night, and the following morning no paralysis of the respiratory muscles could be made out. He was acutely ill with an elevated temperature for five days. The other two patients (patients 4 and 5) had paralysis of the diaphragm and weakness of the intercostal muscles. Both recovered after several days of artificial respiration in a respirator. They had difficulty in swallowing for twenty-one and twenty-seven days, respectively.

The fourth patient was a youth, aged 19, who had prolonged periods of hyperpyrexia for which we found no satisfactory explanation. When he was admitted to the hospital he was aphonic, had paralysis of the soft palate and was unable to swallow. During the first few days he was delirious at times. His breathing was frequently jerky, irregular and shallow, suggesting some injury to the respiratory center. He was not placed in a respirator and gradually improved. On the thirty-sixth day of his illness he began to swallow and retain food.

The fifth patient (patient 2), the youngest in this group, was 3 years of age. He was unable to swallow for seventy-one days, even though the paralysis was not as widespread as in some of the other patients. Except for two days the child received his fluids and nutriment for a month either intravenously, subcutaneously or rectally. During this time the child weathered a bilateral pneumonia.

The patients with prolonged difficulty in swallowing were reexamined several months after discharge from the hospital. The details are given in the abstracts of the case records. In general, the patients experienced some slight difficulty in swallowing for a month or two after going home. All of them were able to swallow well after three months. Some complained of an increased susceptibility to colds. Excessive salivation or accumulation of more than the usual amount of saliva and mucus in the mouth and pharynx was usually present. In our youngest patient this may have inter-

fered with his speech. Huskiness of the voice was noticed in all the patients and a nasal twang in three. Some residual muscle weaknesses were present in four of the patients.

#### ABSTRACT OF CASES PRESENTING PROLONGED DIFFICULTY IN SWALLOWING

**CASE 1—History**—M. H., a white man, aged 33, admitted to the Willard Parker Hospital, Aug. 25, 1933, had been ill for seven days. On the second day of his illness a nasal voice, nasal regurgitation and difficulty in swallowing developed. Subsequently he noticed a weakness of the left side of the face and on the day of admission was unable to swallow.

At the time of admission he was restless and apprehensive but cooperative. The temperature was 100 F, pulse 120 and respiration rate 30. He had a nasal voice, and saliva continually accumulated in the mouth and pharynx. There was paralysis of the left side of the face and left half of the palate. The tongue deviated to the left when protruded. The chest expansion was poor. There was a generalized muscular weakness and all the deep reflexes were sluggish. The abdominal reflexes were present but the cremasteric reflexes were absent. The patient could not sit up unaided. Lumbar puncture at the time of admission revealed spinal fluid under normal pressure, with 25 mononuclear cells per cubic millimeter, normal content of sugar and slightly increased albumin and globulin.

The foot end of the patient's bed was elevated to permit postural drainage. Secretions that accumulated in the mouth and pharynx were suctioned at frequent intervals. Fluids were given subcutaneously and rectally. August 30 (four days after admission) at 1 a. m., he suddenly became cyanotic and stuporous, breathing was irregular and in gasps. The temperature was 102 F and the pulse 120. There seemed to be a lag of the chest and diaphragm on the right side. He was placed in a respirator and oxygen was administered with only slight improvement. At 9 o'clock he was removed from the respirator. At this time no paralysis of the intercostal muscles or diaphragm could be made out. He showed no improvement for five days, during which the stupor continued, and at times he was irrational. For prolonged periods his breathing was irregular and cyanosis would persist, even though oxygen was administered.

September 5 he began to improve. The temperature came down to 100 F and the pulse to 100. A Levin tube was passed and gavages were given. His general condition continued to improve. September 23 (thirty-fifth day of illness) the tongue protruded in the midline. By October 4 he was up in a wheel chair. His palatal and facial paralyses had improved considerably. October 9 (fifty-third day of illness) he swallowed and retained a little soft food for the first time. The following day a fluoroscopic examination was done after the patient attempted to swallow some barium contrast medium. The barium was taken with considerable difficulty and on fluoroscopic examination was seen accumulated in the back of the pharynx, but some of it gradually trickled down the esophagus. A roentgenogram taken five minutes after the barium was administered is reproduced. The report by Dr. Le Wald is as follows: "There is some evidence of paralysis of the muscles of deglutition shown by the inability of the opaque meal to pass beyond the region of the upper end of the esophagus. There are areas of increased density in both lungs, especially on the right side, indicating possible areas of consolidation, which may be due to the fact that the foreign material and mouth secretions have passed into the respiratory tract on account of the paralysis involving the esophagus. October 11 the patient was discharged to his home."

**Follow Up**—The patient communicated with us, November 1. His general condition was good. Liquids and semisolid food could be swallowed slowly. Mucus still accumulated in the throat but it was not troublesome. The patient returned to the hospital for a check up Feb. 5, 1934, four and a half months after discharge. He had a slightly husky nasal voice and a slight cough. He said he swallowed well but at times this had to be done slowly. He had considerable salivation. Examination revealed paresis of the left side of the palate and a little lag in the movements of the facial muscles of the left side. There was diminished expansion of the right side of the

<sup>7</sup> Shambaugh, G. E. Jr., Harrison, W. G. Jr. and Farrell, J. I. Treatment of the Respiratory Paralysis of Poliomyelitis in a Respirator. *Chamber J. A. M. A.* 94:1371 (May 3) 1930.

<sup>8</sup> Peabody, F. W., Draper, George and Dochez, A. R. A Clinical Study of Acute Poliomyelitis. Monograph 4. Rockefeller Institute for Medical Research, 1912.

chest, with dulness and moist rales over the right upper lobe. He was advised to consult his own physician about the lung condition.

The patient was admitted to the Morrisania hospital, April 6, with a history of poor appetite, weakness, cough, night sweats and loss of weight of six weeks' duration. Clinical and roentgenographic examination revealed a tuberculous process in the right upper lobe. Tubercle bacilli were present in the sputum. Hemoptysis occurred April 15. The temperature rose to 105 F at times, and he died, April 20. There was no autopsy.

**CASE 2—History**—H W, a white boy, aged 3 years, admitted to the Willard Parker Hospital, Aug 13, 1933, on the seventh day of his illness, had an eventful past history. At 2 months of age a bilateral otitis media developed and the discharge continued for a considerable time. At 8 months of age he had a bilateral mastoid operation. In November 1932 he had pertussis and in March 1933 measles. In June 1933 a secondary mastoid operation was performed for recurrence of the otitis media. July 19, 1933, the tonsils and adenoids were removed.

Difficulty in swallowing associated with choking began on the second day of the present illness. On examination at the time of admission the patient was pale, undernourished and acutely ill, with a temperature of 100.8 F, pulse 140 and respiration rate 28. He had difficulty in expectorating mucus and saliva, which accumulated in the throat. He had a nasal voice and his cough was weak. There was an asymmetry of the soft palate. The neck and back muscles were weak. The right patellar reflex was sluggish, and the abdominal reflexes were absent. He was unable to swallow even small amounts of food.

Postural drainage was instituted with suction of the mouth secretions as necessary. Fluids were administered subcutaneously and rectally. Lumbar puncture four days after admission revealed the spinal fluid under normal pressure containing 10 mononuclear cells per cubic millimeter, a normal amount of sugar and slightly increased albumin and globulin. August 17 weakness of the left side of the face and tongue were noticed. During the following week the child's condition remained unchanged. Ten days after admission a gavage was given but it was immediately vomited. August 29 (the sixteenth day in the hospital) the respirations became rapid and labored, the temperature was 101 F, and there were signs of bronchial pneumonia at both bases. Nineteen days after admission a gavage was retained and they were continued until two days later, when one of the feedings was regurgitated. After the regurgitation the patient choked and became cyanotic. The condition improved gradually during the day. The temperature was 101 F. A blood count at this time showed white blood cells 6,400, polymorphonuclears 49 per cent, red blood cells 3,570,000, and hemoglobin 70 per cent. A roentgenogram revealed slight enlargement of both hilar shadows, slight accentuation of the pulmonary markings and some ill defined hazy mottling scattered around the root structures—maybe bronchial pneumonia. A transfusion of 200 cc of citrated blood was given September 12 (one month after admission) a Levin tube was passed, and fluids given through it were retained. Another transfusion of 200 cc of citrated blood was given. The course was uneventful for a month, except for an occasional attack of choking as a result of accumulated saliva in the throat. October 18 (seventy-third day of illness) the patient swallowed for the first time and retained small amounts of soft food and liquids. October 30 the child was discharged. The palatal and facial paralyses had decreased. He was active and walked well, but his voice was still thick and nasal. He swallowed well.

**Follow Up**—The child was brought to the hospital for reexamination three and one-half months after discharge. He had been well since leaving the hospital and swallowed without difficulty. The mother noticed that when the child slept his breathing was noisy. On examination the child was alert and cooperative without any external evidence of paralysis. Movement of the palate was sluggish. There seemed to be a slight excess of saliva in the mouth. There were rhonchi and a few coarse moist rales on both sides of the chest. His voice was slightly husky and there was a tendency to indistinctness. Swallowing was apparently normal.

**CASE 3—History**—D F, a white youth, aged 19, admitted to the hospital on the third day of his illness, had had difficulty in swallowing of two days' duration. On the day of admission he lost his voice. Examination of the spinal fluid obtained before admission contained 150 mononuclear cells per cubic millimeter, a normal amount of sugar and an increased amount of albumin and globulin. At the time of admission the patient was acutely ill, restless and practically aphonic, with a temperature of 104 F, pulse 120 and respiration rate 32. He was unable to swallow and could not cough. His breathing was shallow and at times irregular, but there was no cyanosis. He could not sit up. The only other positive changes were a stiff neck and back and deviation of the uvula to the right.

His course was marked by frequent elevations of temperature to 105 F. Respirations were at times irregular and shallow, but he was not placed in a respirator. Attempts to swallow food were followed by gagging and regurgitation. There was no evidence of aspiration demonstrable by roentgenography. On the thirty-sixth day of his illness he swallowed for the first time and was discharged two days later.

Location of barium contrast medium in case 1 five minutes after an attempt was made to swallow it. Most of the barium remained in the retropharynx and some is seen in the lower part of the esophagus (indicated by arrows). The patient was unable to swallow for fifty-one days preceding the taking of this picture.

**Follow Up**—The patient returned for examination five months after discharge from the hospital. He had gained 20 pounds (9 Kg), felt well and had continued his studies at college. Occasionally salivation seemed slightly excessive. For a time after he left the hospital food had to be well chewed before it could be swallowed. During the last two months swallowing had been apparently normal. Examination revealed a slight asymmetry of the palate. No other muscle weakness could be made out. His voice was slightly husky at times.

**CASE 4—History**—M B, a white girl, aged 9 years, admitted to the hospital on the fourth day of illness had had difficulty in swallowing for two days. At the time of admission she had a nasal voice, regurgitated fluids through the nose and was unable to swallow. There was a unilateral weakness of the face, tongue and palate. The patient could not sit up unaided. Respirations were shallow, apparently owing to weakness of the diaphragm.

Her course to a great extent was similar to that described in the three preceding cases. She had a period of respiratory

distress which necessitated treatment in a respirator for two periods of four and five days each. A roentgenogram taken before the second period in the respirator showed "slight enlargement of both hilar shadows and moderate accentuation of the pulmonary markings." On the twenty-seventh day of illness she was able to swallow for the first time. A week later she was discharged. At the time of discharge she was active, had normal reflexes and ate well. She had a residual paresis of the left side of the face and palate.

**Follow Up**—The child was examined six months after leaving Willard Parker Hospital. A few days after arriving at home she contracted a cold. There was severe coughing with choking spells, and on the third day of illness she was sent to the Bronx Hospital by her family physician. The diagnosis was bronchitis. She gradually improved and was discharged a month later. The mother stated that the child was more susceptible to colds than she had been before she had poliomyelitis. For a time after discharge from Willard Parker Hospital, food occasionally stuck in the throat. This gradually became less frequent and during the past few months swallowing was apparently normal. The child's voice was husky and had a nasal twang. There was an excessive amount of saliva and mucus in the mouth and throat. The movements of the palate and facial muscles on the left side were sluggish. Contractions of the diaphragm and the intercostal muscles were diminished, more on the right side than on the left.

**CASE 5—History**—P. G., a white girl, aged 8 years, admitted to the hospital, Aug. 8, 1933, on the third day of her illness, had a history of irritability, drowsiness, headache, vomiting, nasal voice and nasal regurgitation. At the time of admission the temperature was 103.6 F., pulse 140 and respiration rate 38 per minute. On examination she was well developed and well nourished, with hyperactive deep reflexes and a resistance to anterior flexion of the neck and back. She had a nasal voice. Small amounts of fluids or semisolids, swallowed with difficulty, were soon regurgitated. Spinal fluid contained 270 cells, mostly mononuclears, a slight increase in globulin and a normal amount of sugar.

The following day the temperature was 102 F. There was weakness of the neck and back muscles and the deep reflexes of the lower extremities were diminished. There was difficulty in swallowing saliva, and this was removed by suction. The foot end of the bed was elevated. The patient was fed by nasal gavage. On the third day in the hospital the biceps, triceps and abdominal reflexes were absent. There was marked weakness of the diaphragm, slight respiratory distress and restlessness. Difficulty in breathing increased, and during the night the child was placed in a respirator, where she remained for eighteen hours. Gavage was discontinued and fluids were administered subcutaneously and rectally. After removal from the respirator the patient remained comfortable, even though her breathing was mostly thoracic. She gradually improved and on August 20 (the thirteenth day in the hospital) retained liquids given by gavage. A week later, August 27, she was able to swallow small amounts of fluids. Her ability to swallow increased rapidly. September 1 she was discharged to her home.

**Follow Up**—The child was brought to the hospital for reexamination, Feb. 17, 1934, five and one-half months after discharge. She had been well since leaving the hospital and swallowed without difficulty. A slight huskiness of her voice was due apparently to the accumulation of saliva and mucus in the retropharynx. There were no other residual abnormalities due to poliomyelitis.

#### SUMMARY

Difficulty in swallowing occurs frequently in the bulbar type of poliomyelitis. This is not surprising when one realizes how many muscles and nerves are involved in the complex mechanism of deglutition. Among 123 patients with bulbar poliomyelitis admitted to the Willard Parker Hospital in 1933, 87 had difficulty in swallowing. The condition varied in severity from simple nasal regurgitation of short duration to complete inability to swallow for seventy-one days.

The older patients with bulbar lesions showed a greater incidence of impairment of swallowing than the younger ones. The majority of patients were able to swallow normally again in a week. Five patients were unable to swallow for more than three weeks, a condition that has not been reported previously. The treatment consisted of postural drainage, parenteral administration of fluids, gavage and feeding through a Levin tube, which was kept in place several days at a time. Sedatives were given when necessary. The five patients with prolonged inability to swallow had some residual symptoms several months after leaving the hospital. In each one the voice was slightly husky and there was an accumulation of saliva and mucus in the mouth and pharynx. The ultimate prognosis as regards the inability to swallow is good.

## MENSTRUAL EDEMA

### PRELIMINARY REPORT

J. SHIRLEY SWEENEY, M.D., Sc.D.

DALLAS, TEXAS

Many changes, physiologic and biochemical, take place during menstruation. Women frequently describe subjective effects, such as general exhaustion, irritability and generalized discomfort. A certain percentage of them, and I believe an increasingly smaller percentage, experience no change in their state of being, physical, mental or emotional. My purpose in this paper is to draw attention to a phenomenon that, up to the present time, has received very little attention, as judged by the literature. I refer to an edema that seems to occur only during the menstrual cycle. William A. Thomas<sup>1</sup>

Chart 1—Variations in weight of a woman who gained as much as 3 pounds during the menstrual period. In the charts the arrows indicate the onset of menstruation.

recently reported two cases of extensive, generalized edema that occurred only at the menstrual period. One was admittedly the result of a gross glandular imbalance and responded nicely to glandular therapy. I shall supplement his observations and point out that such a phenomenon is not only limited to women with a clinically recognizable glandular dysfunction but also may be observed, in varying degrees, in presumably normal females.

From the Department of Internal Medicine, Baylor University College of Medicine.  
1. Thomas, W. A. Generalized Edema Occurring Only at the Menstrual Period. J. A. M. A. 101:1126 (Oct. 7) 1933.

There is a certain percentage of ostensibly normal women, with perfectly normal menstrual cycles, with normal flow, who will complain of, or describe if questioned, a peculiar tight, stuffy sensation, usually referred to the abdomen, hands or feet, that they experience either preceding or during menstruation, or both. They will often say that their clothes feel unusually tight or that their hands seem slightly stiff, because of a feeling of swelling in them. Shortly after the period is established or has ceased, these sensations

Chart 2—Variations in weight of a woman who gained as much as 3 pounds during the menstrual period

disappear. My attention was first attracted to this phenomenon about three years ago when observing a moderately obese Jewish woman, while on a weight reduction program, which consisted only of diet restriction. She was losing steadily, when suddenly, without any apparent cause, she gained 7 pounds (3.2 Kg) in from thirty-six to forty-eight hours. She spoke of feeling "bloated" and of being tight, and, on examination, it was found that the skin of her hands was unusually taut and there was a definite pitting edema of the shins. In about two more days, menstruation appeared, which was not abnormal, and her weight rapidly returned to the premenstrual level. The same thing recurred with subsequent periods, except that her premenstrual weight gain varied only from 3 to 5 pounds (1.4 to 2.3 Kg).

This phenomenon was subsequently observed in several other women, one of whom consulted me because of swelling of her feet, legs and hands. This patient was 21 years of age with a perfectly negative family history. She began menstruating at the age of 13, and, after one or two periods, menstruation ceased for about eight months, during which time she gained 20 pounds (9 Kg). When menstruation reappeared, she lost this excess weight rather rapidly. Her menstrual cycles are now quite regular and normal. She had the usual childhood diseases without complications. Her complaints, as just noted, when she presented herself were those of swelling of the face, hands and feet, and stiffness of the hands. She stated that she had always been well except for occasional attacks similar to her present complaint. She had never related them to her menstruation. It was found to be associated only with menstruation. The edema still occurs as a premenstrual effect, and pitting is always demonstrable over her shins and feet. Some months it is more marked than others. Her weight gains vary from 3 to 5 pounds.

The next step in this investigation was directed toward a group of presumably normal women who had previously thought nothing of the phenomenon. The group constituted one of the classes of student nurses

in Baylor Hospital. No particular effort was made to control many of the variables operating in such an observation, since the uniforms and shoes worn by the students are of the same sort from day to day, and there is practically no shift in daily habits over a short period of time. A total of forty-two of the nurses recorded their weights at the same hour each day and on the same scales. Their observations were started about ten days before their expected menstruation and obtained daily throughout their period, and for approximately ten days following the cessation of menstruation. Out of the forty-two there were approximately 30 per cent of the students who showed a gain of as much as 3 or more pounds during or about their menstruation cycle. Some of the girls showed no change in their weight and a few showed a loss of a pound or two. Several of those who gained a few pounds spoke of a "tight" and "stuffy" feeling, especially referable to their bodies (that is, their clothes felt tighter on them), hands and feet. A few of the girls stated that they had noticed a diminution of urine output at the time, and in some there was an associated slight increase in thirst. The accompanying charts give the curves of those who gained weight.

The explanation of this phenomenon is not clear. Apparently it is to be found only in a certain percentage of women, and there seems to occur a shift in water balance, varying from an unnoticed slight gain in weight, though often a subjective feeling of fulness or tightness, to a retention sufficient to cause a frank pitting edema. Just what the mechanism of the process may be is unknown. There may be some associated disturbance of the sympathetic nervous system. This seems likely in view of the fact that there have been observed other phenomena associated with menstruation, such as a premenstrual elevation of temperature, thought to be a result of some participation of the

Chart 3—Variations in weight of a woman who gained as much as 3 pounds during the menstrual period

Chart 4—Variations in weight of a woman who gained as much as 3 pounds during the menstrual period

sympathetic nervous system. There may be a disturbance in the relation of some of the blood metabolites, such as sodium chloride, or the proteins. Further investigation is in progress in an effort to explain this queer disturbance in water balance, which seems associated with some clinically unrecognizable endocrine imbalance.

#### SUMMARY

The weight of forty-two normal, healthy young women was recorded before, during and after men-

stration Approximately 30 per cent of these women showed a gain of 3 or more pounds sometime during the menstrual cycle, usually just before the period was established. Other cases showed a true pitting edema. This phenomenon may be due to some endocrine disorder or disturbance of the sympathetic nervous system rather than to changes in the blood constituents or to renal insufficiency.

## SYMMETRICAL SEROUS SYNOVITIS (CLUTTON'S JOINTS)

CONGENITAL SYPHILIS AND INTER-  
STITIAL KERATITIS

JOSEPH V. KLAUDER, MD  
AND

HAROLD F. ROBERTSON, MD  
PHILADELPHIA

Although other writers (Riche<sup>1</sup>, Virchow,<sup>2</sup> Foster<sup>3</sup>) described synovitis of the knees in patients with congenital syphilis, it was not until 1886 that Clutton<sup>4</sup> fully described the condition and associated it with congenital syphilis. Clutton wrote "I have never seen both knee joints filled with fluid causing scarcely any pain or discomfort, whilst other joints remain quite free from any signs of inflammation except in cases where there were complete evidences either past or present of hereditary syphilis."

Since the publication of Clutton's paper the condition has been known as Clutton's joints.

Although this type of synovitis is a valuable and frequent symptom of congenital syphilis, it has not received the attention it deserves. Many textbooks on surgery and on disease of children by American authors make no mention of it or discuss it briefly. It is briefly described in most textbooks on orthopedic surgery, usually as a variety of syphilitic arthritis. Reference to the condition is more frequent in the foreign literature, and it is described more fully in textbooks by foreign writers. It is variously termed symmetrical synovitis, symmetrical serous synovitis, hydrarthrosis, hydrops, painless effusion of the knee joints and Clutton's joints. The eponym is rarely used by American writers.

"Clutton's joints" refers to a painless hydrarthrosis, which is not tender and is unassociated with bone changes. It usually involves the knee and may be unilateral but is more frequently bilateral. A synovitis is the primary and most important pathologic process. The condition is seen for the most part in syphilitic children and is the most common form of syphilitic change in the joints in the congenital variety of the disease. Syphilis of the joints occurring in infants is represented by inflammation secondary to involvement of the neighboring epiphysis. Serous synovitis (Clutton's joints) in adults the subjects of acquired syphilis is uncommon and usually precedes or accompanies the secondary eruption. Such cases have been reported by

Gate and Charpy,<sup>5</sup> Montpellier and Lacroix,<sup>6</sup> Wile and Senear<sup>7</sup> and others. In the series of 165 cases of primary or secondary syphilis reported by Wile and Senear, hydrarthrosis was present in two, both knees were affected in one, and both ankles were affected in the other.

Symmetrical synovitis of children is characterized by its insidious onset. First one joint is affected, and after an interval of months, or rarely of years, the corresponding joint on the opposite side of the body becomes involved. The knee is the site of predilection. In our series of 363 patients with congenital syphilis, sixty-three had Clutton's joints, and the knee was involved in all. Two patients had a concomitant involvement of the elbow. In the forty-three cases reported by von Hippel,<sup>8</sup> the knee joint was involved forty-one times, and in thirty-five cases it was the only joint attacked. The elbows, wrists and fingers were the other joints involved. The knee was affected in all but three of the fifty-four cases recorded by Jeans and Cooke.<sup>9</sup> The elbow was involved four times, the wrist three, the fingers two, and the ankle once. In a case described by Maynard,<sup>10</sup> the knees, ankles, elbows and wrists were involved consecutively. Although some writers state that the hip or shoulder may be involved, we know of no recorded instance of such involvement.

The process is almost invariably painless and apart from the swelling usually gives no indication of its presence. At times there is slight or moderate pain, and the patient may limp. In one of our patients the pain disturbed sleep, and a few complained of some stiffness of the affected joint. A small number of our older patients, the mothers of the younger patients, were aware of a swollen joint. In view of the insidious onset and the lack of subjective symptoms, it was not possible in our series, to determine the duration of the condition.

At the time of examination, the majority of patients with Clutton's joints present a bilateral involvement. In our series of sixty-three cases, both knees were involved in thirty-one, only the right knee in eight, and only the left knee in five. In patients with bilateral involvement, one knee is more swollen than the other. The swollen joint is distended with fluid but is not tense, and on palpation it gives a sensation of flaccid fluctuation. The swelling frequently extends above the patella, and patellar ballottement is obtainable. There is no enlargement of the ends of the bones. There is no tenderness or heat in the joint, and the overlying skin is not red. At times the synovial membrane feels thickened. The joint movement is free except for a slight limitation when there is an excess of fluid. There is no disturbance of function and there is no muscular atrophy. Creaking is not elicited by manipulation. In our two patients with involvement of the elbow, movement was impaired. One of our patients, with swelling of both knees, did esthetic dancing. The illustrations are reproductions of photographs of Clutton's joints taken at different angles.

4 Clutton H H. Symmetrical Synovitis of the Knee in Hereditary Syphilis. Lancet 1: 391 1886.

In rare instances the effusion develops suddenly Dunlop<sup>11</sup> reported the sudden appearance of Clutton's joints in a patient who was receiving treatment for interstitial keratitis. In two patients of our series, the symmetrical synovitis appeared, following injury to the knee. Other writers have observed a similar occurrence.

#### AGE INCIDENCE

The majority of patients with Clutton's joints are between the ages of 8 and 15 years. In von Hippel's series of forty-three cases, eight patients were below the age of 5 years, and one was in the age range of 21 to 25 years. The oldest patient in Clutton's series was 20 years of age. In our series the majority were from 8 to 15 years. This fact will be more fully discussed later.

#### ROENTGENOGRAPHIC EXAMINATION

No changes in the bone are seen. The picture merely shows a distention of the joint.

#### PATHOLOGY

The reported instances of pathologic examination of tissue removed from an involved joint are few. D'Arcy Power,<sup>12</sup> who has performed arthrectomies on patients with Clutton's joints, states that a considerable proportion of the cases show definite pathologic changes, which he describes as follows: The synovial membrane is infiltrated and studded with gummas and is everywhere thickened and much more vascular than normal. Villous processes grow from the endothelial aspect of the synovial membrane. The synovial fringes are especially infiltrated, hanging down into the joint and filling its cavity with a soft, gelatinous material, presenting a soft, reddish, elastic appearance. In the center it is grayish white and caseated, resembling the granulation tissue of tuberculous disease. In some cases, nodes are felt in the capsule of the joint, which give it a firm and almost cartilaginous feeling, while in others the synovial membrane is only a little thickened and hyperemic. In cases of the latter type the condition is true hydrops articuli, or synovial dropsy.

Borchard<sup>13</sup> examined microscopically the synovial membrane removed from the knee of a woman, aged 29. Clinically, both knees were swollen, the synovial membrane was palpably thickened and movement was impaired and painful. A polypous gumma was found which involved the capsular ligament. The fringes of the synovial membrane were swollen and contained small gummas. Microscopic examination showed gummatous formations. Borchard believes that acute synovitis causing an acute hydrarthrosis is seen only in the secondary stage of syphilis. He contends that other forms of hydrarthrosis of syphilitic origin are expressions of gummatous synovitis and are seen in patients with congenital syphilis and in the tertiary stage of acquired syphilis.

#### DIFFERENTIAL DIAGNOSIS

It becomes apparent that what is clinically Clutton's joint may represent pathologically a mild inflammation of the synovial membrane or more pronounced changes with gummatous formation, and clinically it may be difficult to determine when a simple synovitis ends and a gummatous synovitis begins. It is probable that the

difference in the degree of pathologic involvement accounts for the variable course of the disease, the uncertain response to treatment and for the fact that the symptoms described by different writers are somewhat varied. Gummatous synovitis is less common than symmetrical serous synovitis. The clinical picture of gummatous synovitis resembles that of tuberculous synovitis, from which it is differentiated by the following features: It is more likely to be symmetrical and less likely to involve a single joint. Pain, impairment of movement and muscular atrophy of the limb are less pronounced than in tuberculous synovitis. In addition, patients with tuberculous synovitis have sudden pains at night, so-called night screaming, and in the later stages of the disease in cases in which the knee is involved there occur triple displacement, flexion, displacement backward, and rotation outward. These features are absent in cases of gummatous synovitis.

Fig 1—Clutton's joints in a boy with interstitial keratitis. Both knee joints were distended with fluid the right more than the left. Patellar ballotement was elicited on both sides. Thickening was palpable beneath the patella. Motion was not impaired. The patient complained of aching of the knees after skating or walking a considerable distance.

#### COURSE IN UNTREATED AND TREATED PATIENTS

The course of the disease in untreated patients is chronic, remaining unchanged for months and at times for years. Relatively few patients with Clutton's joints are seen after the age of 20. The process tends to terminate in a spontaneous recovery, the involved joint becomes normal. In the case reported by Soupault and Marceron<sup>14</sup> the bilateral effusion in the knee joints appeared at the age of 10 years and persisted for three years.

The response of symmetrical synovitis to antisyphilitic treatment is variously described by the different writers. The majority state that the response is gradual. The fact that mercury and iodides do not have

<sup>11</sup> Dunlop G H Syphilitic Synovitis in Children Edinburgh M J 58 516 1904

<sup>12</sup> Power D Arcy A System of Syphilis ed 2 London Hodder & Stoughton 2 60 1914

<sup>13</sup> Borchard Ueber luetische Gelenkentzündungen Deutsche Ztschr f Chir 61 110 1901

<sup>14</sup> Soupault and Marceron Hydrarthrose syphilitique Bull Soc franç de dermat et syph 29 380 1922

the same effect in this condition as they do in acquired syphilis is stressed in Clutton's original report. Other writers give the impression that antisyphilitic treatment produces a striking improvement. Dunlop speaks of almost miraculous improvement after mercury and iodide therapy. On the other hand, Sutherland<sup>15</sup> writes that "the affection, like interstitial keratitis, tends to run a prolonged course over several years it may be,

Fig. 2—Clutton's joints in a boy with interstitial keratitis. This was the most pronounced case in our series. There was considerable swelling of both joints, thickening of the synovial membrane and slight impairment of motion. The patient complained of slight pain in both knees. After antisyphilitic treatment the swelling gradually disappeared in the course of about one year.

with temporary improvement, with possibly a period of cessation, and then a relapse, and that no treatment, mercurial or otherwise, will have any direct effect." Barrett<sup>16</sup> reports the case of a girl, aged 5 years, with symmetrical synovitis involving both knees, ankles, wrists and elbows. The course was chronic, the disease persisting despite antisyphilitic treatment.

An immediate effect of antisyphilitic treatment was observed in only a few of our patients. Generally, the swelling of the joint gradually disappeared during a period of months or in some cases a year or longer after treatment was started. The prompt improvement and the disappearance of lesions, which invariably result from antisyphilitic therapy in the other forms of syphilis, with the exception of interstitial keratitis, do not occur in cases of Clutton's joints. Because symmetrical synovitis tends to disappear spontaneously, it is difficult in some cases to ascribe a curative effect to treatment. We believe, however, that treatment shortens the course of the process. In only a limited way are we inclined to share the opinion of Sutherland.

In all our cases the effusion eventually disappeared and the involved joints became normal. We have never observed relapse or ankylosis of the joint, which have been noted by some writers. Ankylosis is probably the result of syphilitic arthritis associated with involvement of the neighboring bones. This type of syphilitic arthritis should not be confused with symmetrical synovitis or Clutton's joints.

In some of our cases we employed rest of the joint, and the application of splints or casts in addition to

antisyphilitic therapy. These measures were ineffective. This conclusion agrees with the experiences of others. Surgical intervention was unnecessary in our cases.

#### INCIDENCE OF CLUTTON'S JOINTS IN CONGENITAL SYPHILIS, ITS ASSOCIATION WITH INTERSTITIAL KERATITIS

Most authors stress the association of Clutton's joints with interstitial keratitis and state that the joint condition usually precedes the keratitis. In Clutton's series of thirteen patients with symmetrical synovitis, nine had interstitial keratitis. Thirty-five of the forty-three patients with symmetrical synovitis studied by von Hippel showed interstitial keratitis. Almost all other reports concerning Clutton's joints embrace a small number of patients, the majority of whom had an associated interstitial keratitis. It would appear that Clutton's joints are seldom unassociated with interstitial keratitis.

Jeans and Cooke<sup>9</sup> studied the association of syphilitic arthritis with syphilitic keratitis in a large series of cases. In fifty-four cases of arthritis, keratitis was present in 42 per cent. They state that this incidence is relatively high. The incidence of keratitis in 329 active cases of syphilis was nearly 60 per cent. In ninety-three cases of keratitis, arthritis was present in 12 per cent. Since arthritis was present in 16 per cent of all children over 2 years of age with clinically active syphilis, they state that arthritis is certainly no more common in patients with keratitis than in others. The figures of Jean and Cooke relative to the incidence of arthritis included all types of joint cases. The most common variety, however, was symmetrical synovitis of the knee.

In our study we determined the incidence of Clutton's joints among patients with congenital syphilis,

Fig. 3—Clutton's joints in a boy with interstitial keratitis. Both joints were moderately distended with fluid, the left more than the right. Motion was not limited and there were no subjective symptoms.

divided into three groups. The first group included 250 patients with interstitial keratitis. Clutton's joints were present in forty-five patients, or 18 per cent. The second group included patients with ocular lesions of syphilis other than interstitial keratitis. Among fifty-three patients, nine (17 per cent) had Clutton's joints.

<sup>15</sup> Sutherland, G. A. *The Treatment of Diseases in Children*. London: Oxford Medical Publications, 1913, p. 65.  
<sup>16</sup> Barrett, J. B. *Case of Syphilitic Synovitis*. *Brit. J. Child Dis.* 6: 102, 1909.

The third group included patients with inactive congenital syphilis without ocular manifestations. Nine (15 per cent) of the sixty patients included in this group had Clutton's joints. Most of the patients in this group were the brothers and sisters of patients with interstitial keratitis. All had positive Wassermann reactions, excepting two, both of whom had Clutton's joints. One of these patients showed other stigmas of congenital syphilis. These two were the only instances of negative Wassermann reactions encountered in the entire series of patients with Clutton's joints.

In our total number of 363 patients with congenital syphilis the incidence of Clutton's joints was 17.3 per cent. We demonstrated a slightly greater incidence of the condition in patients with interstitial keratitis than in other patients with congenital syphilis.

The various authors differ in their statements regarding the frequency of Clutton's joints in patients with congenital syphilis. For example, it was 7 per cent in 292 cases reported by Leo,<sup>17</sup> in von Hippel's study it was 56 per cent, and in Fournier's series of 212 cases it was 39 per cent. The statistics of Jeans and Cooke have been quoted.

In a discussion of the association of Clutton's joints with interstitial keratitis it is pertinent to compare the sex and age incidence of the two conditions. It is well known that interstitial keratitis is more common in females and it is most frequent between the ages of 8 and 15 years. In our series of 250 patients with interstitial keratitis, the youngest was 3½ years and the oldest was 44, 50 per cent were between the ages of 8 and 17 years and 70 per cent were between the ages of 8 and 22 years. Sixty-three per cent of the patients were females and 37 per cent were males, a sex distribution almost identical with that of the original 100 cases reported by Hutchinson. In our series of sixty-three cases of Clutton's joints, the youngest patient was 5 years and the oldest was 35 years, 57 per cent were between the ages of 8 and 15 years, 77 per cent were between 8 and 20 years. The ratio of females to males was exactly the same as that of interstitial keratitis. The age and sex distribution of the group of patients with interstitial keratitis and without Clutton's joints showed little variation from that of the group with Clutton's joints.

There is a peculiar susceptibility of the osseous system and of the cornea in congenital syphilis. Interstitial keratitis and involvement of the bones and the joints are the most outstanding manifestations of active syphilis in infants and children. There is a striking similarity between symmetrical synovitis and interstitial keratitis. Both conditions are characteristic of congenital syphilis, occur most frequently in the same age range and affect females more frequently than males.<sup>18</sup> The involvement is unilateral at first in each condition and an interval of time elapses before the commencement of symptoms on the second side. One eye or one joint is involved to a greater extent than its mate. Both processes pursue a chronic course and produce little

or no destructive changes in the tissues. Both conditions respond very slowly to antisyphilitic therapy. Symmetrical synovitis may appear in the second joint after the administration of antisyphilitic treatment in a manner comparable to that in which interstitial keratitis not infrequently appears in the second eye after the commencement of treatment. This phenomenon is unique in the domain of syphilology. Finally, both conditions may appear after trauma.<sup>19</sup> In our two patients in whom symmetrical synovitis appeared after injury to the knees, interstitial keratitis developed after a brief interval. This sequence is in line with the statement of most observers that the development of symmetrical synovitis usually precedes that of interstitial keratitis.

#### INCIDENCE OF CLUTTON'S JOINTS COMPARED WITH THAT OF OTHER STIGMAS OF CONGENITAL SYPHILIS

The incidence of Clutton's joints (18 per cent) was compared with the incidence of other stigmas of con-

Fig. 4.—Clutton's joints much less pronounced than in the preceding illustrations.

genital syphilis in the group of 250 patients with interstitial keratitis. The incidence of other stigmas was as follows: Hutchinson's teeth, 17.5 per cent, other abnormalities of the teeth, 27.5 per cent, chronic periostitis of the tibia (the saber-shaped or Fournier's tibia), 29 per cent, facies of congenital syphilis, 45.5 per cent. The facies was described as suggestive in 8 per cent.

It is interesting to note that the incidence of Clutton's joints in our study was the same as that of Hutchinson's teeth. Other writers, notably von Hippel, have emphasized this fact and suggested that symmetrical synovitis could appropriately displace deafness in Hutchinson's relatively uncommon triad of interstitial keratitis, deafness and notched teeth. Interstitial keratitis, notched teeth and symmetrical synovitis are much more frequently associated.

17 Leo F. Ueber die Entwicklung kongenital luescher Kinder und gesunder Kinder luescher Mutter. *Dermat. Wehnschr.* 94: 787 (June 4) 1932.

18 The many curious features of interstitial keratitis constitute the most remarkable phenomena in syphilology. The most noteworthy feature is the invariable involvement of the second eye even after antisyphilitic treatment has been instituted. It is not pertinent to discuss here the explanations that have been offered; it is interesting to note, however, that Hutchinson apparently considered that the two eyes act as one organ, as he stated in explanation that symmetrical diseases are always manifested first on one side and simultaneous bilateral involvement is rare. Further discussion of Hutchinson's opinions and teachings is furnished by Klauder J. V. *Jonathan Hutchinson Medical Life* 41: 313-326 (June) 1934.

19 A detailed discussion of the relation between interstitial keratitis and trauma is furnished by Klauder J. V. *Ocular Syphilis: Interstitial Keratitis and Trauma. Clinical, Experimental and Medicolegal Aspects.* *Arch. Ophth.* 10: 302-328 (Sept.) 1933.

In a comparison of the incidence of symmetrical synovitis to other stigmas of congenital syphilis it should be observed that, unlike other stigmas, synovitis is not permanent, its incidence is in relation to the age of the patient. Symmetrical synovitis is a valuable sign of congenital syphilis. Examination of the joints, especially the knees, should not be neglected in the search for evidence of congenital syphilis. Clutton's joints are of prognostic significance. Every child with congenital syphilis is a potential candidate for interstitial keratitis,<sup>20</sup> especially in the age range already discussed. It appears that the presence of Clutton's joints increases the likelihood of the development of interstitial keratitis.<sup>21</sup>

## THE SUGAR TOLERANCE IN SIBLINGS OF JUVENILE DIABETIC PATIENTS

HARRY S. MACKLER, MD

AND

ALFRED E. FISCHER, MD

NEW YORK

It is generally accepted that diabetes mellitus is a familial or hereditary disorder of metabolism. In fact, Pincus and White<sup>1</sup> have been able statistically to show that diabetes is inherited as a mendelian recessive characteristic. Experimental proof of this fact has been brought forward by Cammidge.<sup>2</sup> He was able, by mating strains of mice having a high fasting blood sugar with those having normal blood sugars, to transmit the hyperglycemia to succeeding generations as a recessive quality. Cammidge suggested that in human beings the same blood sugar conditions might occur. Joslin and his co-workers<sup>3</sup> have shown that new cases of diabetes mellitus are continually being encountered in the families of diabetic children. They have shown a progressive incidence in new cases in those families from year to year.

Because of the familial tendency of diabetes a study was started in 1928 with the purpose of detecting early impairment of sugar tolerance in siblings of diabetic children by means of the dextrose tolerance test. A somewhat similar study had been undertaken by Sherrill,<sup>4</sup> who was probably the first investigator to study the carbohydrate tolerance of relatives of diabetic patients. He studied forty relatives of twenty-three diabetic patients. Twenty-two of these were 20 years of age or older while eight were from 3 to 20 years of age. Twenty-one of the forty cases showed what the author considered to be an impairment of sugar tolerance. Of the eight patients under 20 years of age, three had a high blood sugar which persisted for two hours following the dextrose meal. The other five

showed normal curves. Twin girls, aged 6 years, showed diabetic types of curves. Further reports on these cases are not available.

In 1931 Sehestedt<sup>5</sup> reported on the sugar tolerance of six siblings of three juvenile diabetic patients. He employed three types of sugar tolerance tests, the one comparable to our own in which one dose of dextrose was given, the second consisting of three doses of 20 Gm each of sugar at intervals of one hour, and the third, 25, 50 and 75 Gm of bread given one hour apart. The results of the first test, which is comparable to that which most workers employ, showed that four of the six children had fairly normal curves. Two gave an irregular response. One of these a year later again showed a slightly elevated type of curve but the patient in the meantime had not developed diabetes. Sehestedt's single case is the only report we could find in the literature of reexamination of siblings of diabetic children who had been previously tested for their dextrose tolerance.

John<sup>6</sup> reported on 1,100 routine dextrose tolerance estimations on adult patients admitted for various complaints to the Cleveland Clinic. Of 104 cases with a diabetic family history, 44.2 per cent gave a non-diabetic type of curve while 55.7 per cent gave a diabetic type of curve. The high percentage of diabetic curves cited by Sherrill and John made us wonder in how many patients who had the so-called diabetic type of blood sugar curve diabetes subsequently developed.

John classified sugar tolerance curves in four ways:

- 1 Very little or no rise, interpreted as increased tolerance.
- 2 A rapid rise and equally rapid fall (one to one and one-half hours), interpreted as normal tolerance.
- 3 A slower and higher rise and a slower fall (two and one-half to three and one-half hours), interpreted as decreased tolerance, a prediabetic type of curve.
- 4 A slow, high rise and equally slow descent (three and one-half hours or more), interpreted as a diabetic type of curve.

This classification brings up the question as to whether one is justified in considering as prediabetic those individuals who may show a delayed return to normal following a dextrose meal. John<sup>7</sup> stated that he intended to restudy the curves of nondiabetic subjects in order to determine whether it is only the person with a reduced tolerance to carbohydrate, as shown by the test meal, who eventually becomes diabetic.

Our study was likewise undertaken with the idea of following the siblings of the diabetic children under our care for some time after their dextrose tolerance had been studied. Originally, thirty siblings of twenty diabetic children were studied. Twenty of these were Jewish and ten non-Jewish. Twenty-one of the thirty children were reexamined in 1934.

### TECHNIC

The Kuttner modification of the micro-Folin-Wu test for blood sugar was used. All estimations were made on capillary blood soon after its withdrawal. Studies were begun after a fourteen hour overnight fast. Determinations for dextrose were done on the samples withdrawn in the fasting state and at intervals of one-half, one, one and one-half, two and two and one-half hours after the ingestion of the dextrose solution. We estimated the amount of dextrose to be

20 The incidence of congenital syphilis in the general population as given by different writers ranges from 0.5 to 3 per cent and the incidence of interstitial keratitis among patients with congenital syphilis ranges from 25 to 50 per cent.

21 Since this paper was written we have observed a girl aged 20 with interstitial keratitis. The diagnosis of interstitial keratitis of congenital syphilis was not made until about one month after its onset. One month antedating the appearance of the keratitis one elbow became the site of a Clutton's joint. There were no other stigmas of congenital syphilis. Correlation of the joint condition with the keratitis would have promoted early diagnosis of interstitial keratitis of syphilitic origin. From the Children's Diabetic Clinic service of Dr. Bela Schick, Mount Sinai Hospital.

used by means of the formula devised by Pirquet. This utilizes the sitting height squared as the index of the nutritional surface area. Fries and Kohn<sup>8</sup> found this method to be satisfactory for estimating the dextrose to be administered when determining the sugar tolerance curve in children. In terms of grams of dextrose per kilogram of body weight this amounted to from 0.96 to 1.85 Gm per kilogram of body weight (column 11 in accompanying table). Gilchrist<sup>9</sup> found that the blood sugar curves in children, when given 1 Gm or more of dextrose per kilogram of body weight, were similar to those found in adults.

## RESULTS

The siblings of our diabetic children were on the whole slightly overheight and overweight when compared to average normal standards.<sup>10</sup> In only a few instances, however, was overgrowth striking.

Of thirty sugar tolerance tests, twenty-five were normal, three gave a relatively high figure at the one hour reading, and two of these were still high after

in 1934. Their curves at this time were both normal. L. T.'s fasting blood sugar was 65 mg, which rose to 120 mg at the end of one and one-half hours and fell to 75 mg at the end of two hours. M. T. had an even lower curve.

It was with particular interest that the urine of the siblings was reexamined in 1934, six years after the dextrose tolerance tests. Urine was obtained from twenty-one of the thirty children whose curves are tabulated, including the five who had slightly elevated sugar tolerance curves. No glycosuria was found in any specimen. All three children who were more than 5 per cent overheight for their age had normal blood sugar tolerance curves when they were reexamined. In addition to being siblings of a diabetic child they were markedly overgrown but as yet have shown no indication of diabetes. We intend to repeat the dextrose tolerance tests of all these siblings after a few more years.

In our series of fifty-seven juvenile diabetic patients, some of whom have been observed for as long as

§ Twins.

one and one-half hours. All five, however, were normal after the two and one-half hour period. It is interesting to call attention to the fact that in sixteen instances the two and one-half hour reading was below the fasting blood sugar. This phenomenon has been observed by others in normal individuals. No indication of decreased tolerance was noted in subject 29, a girl whose two brothers and one sister have diabetes. Subject 9, who was recuperating from an acute mastoiditis at the time of the test, had a curve within normal limits. One of heterozygous twins, L. T., subject 25, showed a rather high curve, her blood sugar at the end of one and one-half hours being 140 mg. This child as well as M. T., her twin sister, subject 24, was retested early

nine years, no brother, sister or parent developed diabetes during that time. In some instances, to be detailed in a subsequent paper, a close relative became diabetic. Since nine years is only a fraction of the average life expectancy, these observations are of limited significance, for siblings and parents of juvenile diabetic patients can develop diabetes at any time over a period of years. It was hoped, however, as indicated by other workers in this field, that it might be possible to detect a predisposition to diabetes by means of the sugar tolerance test. This has not been the case thus far in thirty siblings of juvenile diabetic patients as indicated by the curves as well as the subsequent histories of these patients. Since the onset of diabetes in children and in adolescents is, as a rule, rather sudden, we feel that the sugar tolerance method does not hold much promise as a means for detecting early cases of diabetes in childhood. This method might be

of value in older patients in whom the onset of diabetes is frequently insidious

#### CONCLUSIONS

1 Thirty siblings of juvenile diabetic patients were examined. Their sugar tolerance curves were within normal limits

2 Of these, twenty-one were reexamined six years later. In none of them had diabetes developed. We were able to ascertain that the other nine, although they were not examined, had no symptoms of diabetes

3 Five siblings whose curves suggested a decreased tolerance for carbohydrate in 1928 were retested in 1934. The curves gave normal values and showed no prediabetic tendency

### INTRASPINAL (SUBARACHNOID) INJECTION OF ABSOLUTE ALCOHOL

FOR THE CONTROL OF PAIN IN FAR ADVANCED MALIGNANT GROWTHS

HARRY C SALTZSTEIN, M.D.  
DETROIT

"To the lay mind, carcinoma denotes pain"<sup>1</sup> Other diseases have just as long a period of disability with no hope in many cases of averting a fatal outcome, e g, heart disease, chronic arthritis, tuberculosis, but they are not the scourge that cancer is because friends and relatives do not see the months of severe uncontrollable pain and distress that are so common in terminal cancer cases

In 1931 Dogliotti<sup>2</sup> reported that he had relieved forty cases of pain in the lower part of the back, the pelvis and the legs due to various conditions (chronic arthritis, sciatica, abdominal tabetic crises and the like) by intraspinal injections of absolute alcohol

Yeomans<sup>1</sup> reported its use in seven cases of malignancy presenting lower abdominal and rectal pain

I have used the method in eleven cases. My purpose in presenting the results in this small series is that the field for usefulness of this procedure must be very large, and I hope that others will try it

I have very little to add to Yeomans' description of the technic

For visceral and abdominal pain, injection may be made between the first and second lumbar vertebrae. With the patient resting on the side opposite to that affected, the alcohol in a tuberculin syringe is injected very slowly, drop by drop, a total of from 0.2 to 1 cc, varying with the nature of the case. The patient remains in this position for twenty minutes and then is rolled on his back, where he rests for two hours. Following the injection, zones of anesthesia or hyperesthesia may appear, and cutaneous tendon reflexes may be diminished or lost. The motor effects are mild, but temporarily the knees may bend under the patient when he stands or tries to walk. These phenomena disappear in a few hours or, at most, days. Usually there is no disturbance of bowel or bladder function, although in one of our cases there was retention of urine

If the pain is not relieved in a fortnight, the injection is repeated at the same level of the spinal cord, but with the patient resting on the opposite side. The rationale of the treatment is that absolute alcohol, being lighter than the spinal fluid, rises and follows the line of exit of the spinal nerves, hence the necessity of keeping the patient immobilized for some time after the injection. The spinal fluid is at first under increased

pressure and the cell count is increased, but it returns to normal in ten days. The relief of pain on the average lasts for six months

The procedure is especially useful in far advanced cervical cases. Frequently radium and x-rays stop the vaginal bleeding, and, though the local lesion remains cured, the disease continues to progress in the retroperitoneal glands. In some of these cases within two to four months low lumbar distress and pain on exertion begin, gradually becoming more severe. Soon there is a continuous viselike backache, sometimes with pain down one buttock or leg almost as severe as the root pains of tabetic crises

This is likewise true with rectal carcinoma, but not so often, probably because the spread of rectal carcinoma is more apt to involve the glands alongside the iliac veins and abdominal aorta rather than the glands in the lowermost retroperitoneal tissues, where lie many large nerve trunks

Spinal metastases from breast cancer are often controlled for a time by roentgen therapy and by braces, but the pain later frequently becomes severe. The patient lies in bed without daring to move or even to allow the bedclothes to be changed, because the slightest movement of the back is excruciating

Such pains are difficult to control with drugs. By preventing eating and sleeping, they are often the chief cause of rapid emaciation and progressive deterioration

Chordotomy is not an entirely satisfactory procedure. There is a certain danger of bladder and rectal incontinence and other complications, and many of these patients are too sick or life expectancy is too uncertain to warrant the risk of this delicate operation. Ruth<sup>3</sup> recently stated that "the results (of chordotomy) seem discouraging" considering the risks involved. He recommends 30 per cent alcohol nerve block, carefully studying and plotting out the sensory nerve pathways involved (e g, rectum, second to fourth sacral, bladder, twelfth dorsal to first lumbar). Gilcreest and Mullen,<sup>4</sup> de Takats,<sup>5</sup> and others have also recommended from 15 to 30 per cent alcohol injections into the sacral canal and into the second, third, fourth and fifth sacral foramina for pelvic pain. Sometimes these injections must be repeated each week, and if another segmental nerve distribution becomes involved a different injection must be done. Others have removed the presacral sympathetic nerve (laparotomy). Subarachnoid injection is much more simple than any of these methods and is apparently quite satisfactory.<sup>6</sup>

I have used the method in eleven cases of far advanced malignancy: eight cervical, two spinal metastasis from breast cancer, one cancer of the prostate

5 de Takats Geza in discussion on Ruth<sup>3</sup>

6 Condamine and Arnulf (Treatment of Pain Due to Pelvic Cancer by Injection of Nerves. *Rev de chir Paris* 51:635-650 [Oct] 1932) abstr *Am J Cancer* 20:455 [Feb] 1934) have classified pain in patients with pelvic cancer into three types: (a) limited to perineum and anal regions attributable to the last branches of the sacrococcygeal plexus—relieved by epidural injection; (b) Corresponding to the sacral plexus pain in pelvis with sciatic radiation down the buttock and the posterior surface of the thigh relieved by injection of second sacral root; (c) Corresponding to lumbar and sacral plexus more diffuse pelvic pain and diffuse radiation down genitocrural and femorocutaneous nerves relieved with more difficulty by injection of first and second sacral root plus paravertebral injections along the lumbar nerves. I have recently relieved two patients with rectal carcinoma in whom pain was limited to the coccyx and perineum type a by an epidural injection of the solution that these authors recommend (94 per cent alcohol 20 cc, menthol 0.1 Gm, procaine hydrochloride 0.2 Gm from 1 to 4 cc of this solution is used). Type c I feel is much more simply handled by intraspinal absolute alcohol injection. I have not had any cases that were recognized as corresponding exactly to type b but the point is worth bearing in mind. As noted many of these cases later spread upward and involve more nerves.<sup>4</sup>

From the Mercy Hall Hospital and Tumor Clinic

1 Yeomans F C. Care of Advanced Carcinoma of the Gastrointestinal Tract. *J A M A* 101:1141 (Oct 7) 1933

2 Dogliotti A M. Nouvelle methode therapeutique pour les algies peripheriques. Injection d'alcool dans l'espace sous arachnoïdien. *Rev neurol* 2:485 (Oct) 1931

Concerning ill effects, except for occasional transient signs of intraspinal irritation I have found no immediate ill effects (One patient had mild nausea and headache for two days) There is usually burning for a few seconds as the alcohol is first introduced Transient paresthesias, usually along the outer thigh of the extremity that was uppermost as the injection was given, occurred in several cases In five cases there was weakness of this extremity It disappeared within from two to three days in four patients In the fifth, a far advanced cervix case, it persisted for three weeks but gradually cleared entirely In only one case was there bladder or rectal disturbance following the injection In a woman with extensive spinal metastasis from breast cancer, mild abdominal distention, relieved by enemas, persisted There was also delay in voiding However, there was slight weakness of the left leg and some abdominal distention before the injection, so I thought these symptoms were due to cord involvement of the growth, which was extensive In no instance was there bladder or rectal incontinence such as I have seen after chordotomy

#### RESULTS

In one cervix case the injection was of no benefit Back and leg pains started again twenty-four hours later A second injection, given after ten days, similarly gave relief for thirty-six hours only For the remaining three weeks of life there was excruciating pain in the pelvis, the lower part of the back and the thigh, with fever and leukocytosis Necropsy revealed an extensive infected pelvic mass, part of which was intimately associated with and pressing on the retroperitoneal nerve plexuses In all other cases, relief was instantaneous Pain, frequently of a violent nature, which the patient had complained of for weeks or months, stopped immediately and was gone before the needle was withdrawn In several cases the local lesion has progressed, causing symptoms from bladder irritability, constipation, and the like, but the severe backache has not returned In two cervix cases, the injections were made a few weeks after back pain started and the patients were subsequently cared for at home in relative comfort for a considerable time, the local lesions meanwhile progressing Such cases frequently require prolonged hospitalization, chiefly because of the intractable pain

The method is applicable in terminal cases, with only a few weeks' life expectancy, since the injection is given in bed and it is only necessary to turn the patient over on the side I have not as yet needed to repeat the injection, except in the one case in which two injections were failures In some cases the maximum effect of the injection was not obtained for one or two weeks, transient pains persisting during this period, but gradually easing off

I have used the first or second lumbar interspace Most of my patients have had low back, sacral and pelvic, and sometimes low lumbar pains, with frequent sciatic radiation down the posterior thigh In one case, pain in the right lower thoracic region, reaching to the fourth rib in the nipple line, was considerably improved but not entirely relieved following the injection

#### ILLUSTRATIVE CASES

**CASE 1—Cancer of cervix** The onset occurred in October 1932 with intermenstrual spotting

Examination in October 1933 revealed a severely bleeding cauliflower mass encompassing the entire cervix with extensive involvement of the uterine adnexa and broad ligaments Palliative radiation therapy controlled the bleeding

January 1934, the patient had pains in the lower part of the back, which became increasingly severe, extending down the right thigh and leg as severe root pricks

February 1, the pains were increasingly severe She required one-half grain (0.03 Gm) of codeine,  $1\frac{1}{2}$  grain (0.1 Gm) of phenobarbital or 10 grains (0.6 Gm) of barbitol by mouth, and an occasional hypodermic injection of one-fourth grain (0.016 Gm) of morphine during the course of twenty-four hours

One cubic centimeter of alcohol was injected into the second lumbar interspace There were no immediate symptoms The pain stopped immediately

March 28, the pains in the back and down the leg had disappeared

There is a large sloughing mass in the vagina with severe hemorrhage every week This causes considerable bladder irritability and frequency (direct extension)

The patient is bedridden and the condition is far advanced, but she requires only an occasional phenobarbital or barbitol tablet at night (rarely a morphine tablet)

In this case, severe backache and leg pains of far advanced cancer of the cervix are controlled by injection

**CASE 2—Cancer of cervix** A young woman had had radium treatments in May 1933 Since then she had had repeated hemorrhages Soon discomfort started again In June, pain in the back started, mild at first, becoming gradually more severe At examination in November the patient was severely anemic The foul bleeding cervical mass had to be packed several times because of profuse hemorrhage

She was in severe pain because of pain in the back She would not move in bed She cried and was irritable much of the time She required 2 doses of dilaudid (one-sixteenth grain) 2 grains (0.13 Gm) of codeine, 20 grains (1.29 Gm) of acetylsalicylic acid, 2 grains of phenobarbital and 1 grain of sodium amytal during twenty-four hours

December 3, 0.35 cc of absolute alcohol was injected in the second lumbar interspace There were no immediate symptoms

December 4 she was much more comfortable She could now be moved in bed without discomfort and was much brighter, was interested in the surroundings, and was comfortable She asked for the first time to have her hair arranged

December 13, the patient continued to be comfortable Very little medication was required There was a sudden severe vaginal hemorrhage followed by death

This was a terminal case in which the patient was made comfortable for the final two weeks of life after having required large doses of narcotics and sedatives before injection

**CASE 3—Cancer of breast** Removal of the right breast for cancer had been done in April 1932 In August 1933, severe pain developed in the right hip to the knee and the lower part of the spine and back When the patient was examined in November, she was unable to move in bed Roentgenograms showed pelvic and lumbar bony metastases She required from 3 to 4 grains (0.19 to 0.26 Gm) of codeine, from one-sixteenth to one-eighth grain (0.004 to 0.008 Gm) of dilaudid hypodermically, occasional morphine, acetylsalicylic acid and phenobarbital in twenty-four hours

December 2, 0.5 cc of absolute alcohol was injected in the first lumbar interspace There were no immediate symptoms but there was immediate relief from pain before the needle was withdrawn

December 3 pain on the right side had gone completely There was still slight pain in the left side The patient moved about in bed without pain

December 18 there was occasional pain more paresthesia than actual pain—sometimes in the right leg, sometimes in the left No codeine was required Occasionally acetylsalicylic acid or amidopyrine was given at night

March 15 1934, the patient had no trouble moving her feet in bed She was resting comfortably except that occasionally there was transient pain in the left hip and leg, relieved by codeine one-half grain The pain was not severe enough however, for a second injection

In this case of spinal metastasis from cancer of the breast with considerable pain relief has been obtained for four months The patient was comfortable in bed

NASAL CATHETER ADMINISTRATION  
OF OXYGEN

WITH OBSERVATIONS ON ALVEOLAR SATURATION

M HERBERT BARKER, MD  
CHICAGO

D M PARKER, MD  
PEIPING, CHINA

AND  
GEORGE WASSEL  
CHICAGO

The clinical administration of oxygen is now being employed in many disorders and is being used in the home as well as in the hospital. This has been rendered possible through the improved availability of oxygen and the development of simplified equipment for its administration.

In general, it is considered that the inhaled air must contain from 35 to 55 per cent of oxygen in order to produce therapeutic effects. To attain such oxygen percentages in the inhaled air several methods have been employed, namely the oxygen room, the oxygen tent and the nasal catheter.

The nasal catheter method is a simple means of giving oxygen but it has been criticized by many as being relatively inefficient. Barach<sup>1</sup> obtained a 30 per cent concentration of oxygen in the inspired air of the pharynx by means of the nasal catheter and reported that the oxygen content of the blood of patients with pneumonia could be elevated with a flow of 2 liters per minute. An oxygen concentration of 38 per cent was obtained with a 5 liter flow and Barach concluded that the nasal catheter furnished a very useful method for the administration of oxygen. Palmer<sup>2</sup> felt that oxygen therapy by means of the nasal catheter was effective in relieving mild degrees of anoxemia in "certain acute pulmonary conditions." Waters<sup>3</sup> revived our interest in the nasal catheter method by showing that with a proper pharyngeal insufflation technic an oro-

flow and at different respiratory rates should indicate whether adequate therapeutic concentrations of oxygen in the alveolar air can be obtained by the nasal catheter and the rate at which the oxygen must flow through the nasal catheter to obtain such concentrations. The following study was made to determine the efficiency of the nasal catheter method for administration of oxygen.

METHOD OF STUDY

Three normal adults were used in this study. Standard, soft, urethral catheters, sizes 12 to 14, with extra holes at the tips, were introduced into one nostril until the tip was discernable at the level of the uvula. They were then adjusted to the comfort of the subject by withdrawing slightly and fixed in place with adhe-

The column at the left gives rate of oxygen flow in liters per minute while the percentage of oxygen in alveolar air appears above. As the rate of flow of oxygen is increased in liters per minute an increase of alveolar oxygen saturation occurs. Note that the oxygen saturation curves are essentially straight lines dependent on rate of flow and this saturation is but slightly altered by changes of respiratory rate.

TABLE 1—Effects of Rate of Oxygen Flow and Respiratory Rate on Concentrations of Oxygen and Carbon Dioxide in Alveolar Air

Oxygen Flow per Minute	Percentage of Alveolar Oxygen at Respiratory Rates of				Percentage of Alveolar Carbon Dioxide
	6	16	30	60	
4 liters	34	30	31	30	5.0
6 liters	46	35	37	40	5.2
8 liters	52	40	43	45	5.4
10 liters	62	44	48	49	5.3
12 liters	71	50	52	54	5.2
15 liters	74	56	60	60	5.0

pharyngeal oxygen saturation of 35 per cent could be maintained with a flow of 2 to 3 liters per minute, while with a flow of 10 liters per minute a concentration as high as 74 per cent could be attained.

It would seem that determinations of the alveolar oxygen saturation taken at different volumes of oxygen

sive tape. The flow of oxygen was administered from standard commercial oxygen tanks through a humidifier at 4, 6, 8, 10, 12 and 15 liters per minute. Samples of alveolar air were collected by cutting off the oxygen supply at the end of inspiration and then letting the subject expire completely, at which point air was drawn into modified Douglas bags from the nasopharynx through the same catheter (mouth closed and nasal pincher in place). The control observations on alveolar oxygen and carbon dioxide at various respiratory rates conformed very closely to those reported by Haldane<sup>4</sup> and his co-workers. Several series of determinations of alveolar oxygen and carbon dioxide at various respiratory rates and different rates of oxygen flow were made on each subject on different days. The carbon dioxide concentration in the samples ranged between 4.9 and 6.5 per cent with an average of 5 per cent or over, indicating that we were obtaining samples of the deep alveolar air.

The determinations of oxygen and carbon dioxide were made by means of the modified Haldane instrument and the instrument by the Hays Corporation. The results obtained on each subject checked within surprisingly narrow limits, although an individual variation was noted. This difference was so small that they were all averaged and the charts show clearly the results obtained.

The figures given in table 1 show a rising concentration of oxygen in the samples drawn from the nasopharynx as the rate of flow through the catheter was increased. The individual protocols are omitted because of the similarity of the results obtained in each subject. The table does not include the observations made on

The Linde Air Products Company donated a liberal supply of oxygen for use in these experiments.

the administration of oxygen under 4 liters per minute because the concentrations were below the levels of probable therapeutic effect. The alveolar oxygen saturations were not greatly altered by nasal or oral breathing in a similar series of observations.

The respiratory rate does not seem to affect greatly the alveolar concentration except that with a respiratory rate of six per minute the alveolar concentrations were all found to be increased. The results obtained indicate that alveolar saturations of 35 per cent may be obtained with a rate of flow of about 6 liters per minute and the usual desired concentration of 50 per cent requires a flow of from 10 to 12 liters per minute. This rate of flow was well tolerated for hours at a time. It was our experience that such a flow may be comfortably maintained for from three days to three weeks if the oxygen is well humidified and if the nasal cavity and oropharynx are sprayed at intervals of from one to two hours with liquid petrolatum from an atomizer. It is desirable to cleanse the catheter and to change it from one nostril to the other at least every twelve hours. Oxygen concentrations of 60 per cent or over in the alveolar air required a flow of from 14 to 16 liters per minute. The figures given in the chart are arranged graphically to indicate at a glance the concentration of oxygen in the alveolar air determined by the rate of flow, so that a desired alveolar saturation may be obtained promptly by adjusting the flow in liters per minute as indicated in the column at the left.

Oxygen concentrations of 60 per cent or over in the alveolar air required a flow of from 14 to 16 liters per minute. Some difficulty was encountered in keeping the pharynx from becoming uncomfortably dry when such rates of flow were employed. It is the impression of the observers that such high concentrations of alveolar oxygen, although often required clinically,

the tent, hence the oxygen concentration of the tent atmosphere may be roughly stated as a close index of alveolar oxygen saturation. The respiratory rate did not alter this relation perceptibly. The tent, therefore, is much the more economical method of administering therapeutic concentrations of oxygen from the standpoint of the volume of gas required. This fact, however, must be weighed against the objections of the cost, upkeep and difficulty in operation of the tent as compared to the catheter, as well as the fact that this method is not adapted to the treatment of certain patients, such as those who are delirious or orthopedic, and who may be well supplied by the catheter. Each method has certain advantages and disadvantages, which will be discussed elsewhere.

#### CONCLUSIONS

1 Oxygen saturations of from 30 to 60 per cent in the alveolar air are readily obtained by pharyngeal insufflation with the use of the nasal catheter.

2 Oxygen saturations of 50 per cent in the alveolar air are obtained by nasal catheter only with an oxygen flow of from 10 to 12 liters per minute.

3 Similar observations made in the tent indicate that the alveolar saturation is roughly that of the tent atmosphere.

### TRAUMATIC SUBDURAL HEMATOMA

#### AN EXPLANATION OF THE LATE ONSET OF PRESSURE SYMPTOMS

ROBERT ZOLLINGER, M.D.

AND

ROBERT E. GROSS, M.D.

BOSTON

The clinical and pathologic aspects of traumatic subdural hematoma have received full consideration in many previous reviews. Various authors have emphasized the fact that cranial injury may be attended by little or no symptomatology at the time but that evidence of increased intracranial pressure may develop long after the original trauma. Therefore it is not unusual for these patients to be symptom free for several months before developing signs of an intracranial lesion. Various theories have been proposed to explain the prolonged "latent period." Our studies on a patient with bilateral subdural hematomas offers evidence that satisfies the clinical and experimental requirements as an explanation for the latent period so characteristic of this condition.

It has been generally agreed that the delayed onset of clinical symptoms is dependent on an augmentation in volume of the blood that is entrapped in the subdural space. Some clinicians believe that repeated bleeding accounts for enlargement of the subdural hemorrhage, but there is little pathologic evidence to support this view in the majority of cases. Gardner<sup>1</sup> recently showed that the sac which forms about such a collection of blood has the characteristics of a semipermeable membrane. He believed that the enlargement of the sac depended on the passage of tissue fluids into the

60	52.5	3.00	51.4	4.80

would be difficult to maintain for long periods of time in the average patient without the use of an efficient humidifying equipment. However, no ill effects other than the discomfort described have been noted from any rate of administration.

Similar determinations of alveolar oxygen and carbon dioxide were made on ourselves in oxygen tents. The concentrations of oxygen in the air of the tent was varied from 40 to 65 per cent. The alveolar oxygen concentration was found to be essentially the same as that of the air of the tent. The alveolar oxygen concentrations were found usually to be about 1 to 3 per cent below the concentration of oxygen in

<sup>1</sup> Gardner, W. J. Traumatic Subdural Hematoma with Particular Reference to the Latent Interval. *Arch. Neurol. & Psychiat.* 27: 847-856 (April) 1932.

hematoma as a result of differential osmotic tension existing between whole blood and cerebrospinal fluid when they are separated by a semipermeable membrane. Since the hematoma sac probably forms very rapidly after the original hemorrhage, it is reasonable to expect that any difference in osmotic tension between the enclosed whole blood and the neighboring cerebrospinal fluid would be compensated for in a day or two after the membrane is completed. Therefore, Gardner's

porarily relieved on several occasions by nausea and vomiting. A gradual diminution in vision developed, and on October 5 diplopia was noticed. The symptomatology was that of increased intracranial pressure which had progressed over a period of at least three months without definite localizing signs.

*Physical Examination*—The patient was intelligent, euphoric and talkative. He was in good general physical condition. The pupils were dilated to 7 mm but were equal and regular and reacted to light and in accommodation. There was bilateral choking of the optic disks to 4 diopters. The remainder of the general neurologic examination was essentially negative.

*Laboratory Examination*—Wassermann and Hinton reactions of the blood and ventricular fluid were negative. The total protein content of the ventricular fluid was 20 mg per hundred cubic centimeters and the cell count was 3 lymphocytes per cubic millimeter.

TREATMENT

*Diagnosis*—The diagnosis of a right frontal tumor was made but in the absence of definite localizing signs ventriculography was performed on October 21 under local anesthesia. The right ventricle was tapped, clear fluid was obtained and air was injected. A needle was not passed through the left trephine opening because of a bluish discoloration beneath the dura, which at that time was thought to be a large vein. The ventriculogram showed marked displacement of the third and lateral ventricles to the left. Despite this marked displacement in the anterior-posterior view the ventricles were not distorted in the lateral view. Dr Merrill C Sosman interpreted these observations as indicating an extensive superficial lesion, possibly a hematoma.

*Operation*—A large frontoparietal bone flap was turned down under procaine hydrochloride anesthesia the same day by one of us (R Z). A large encapsulated subdural hematoma was found extending from the frontal region almost to the occipital lobe and triangularly downward toward the floor of the middle fossa (fig 1). The sac was easily peeled from the dura and the underlying arachnoid. A subtemporal decompression was done and the bone flap was sutured back into place. The postoperative course was uneventful except for rather pronounced euphoria.

We recalled the bluish discoloration beneath the dura on the left side at the time of ventriculography, and knowing that subdural hematomas are frequently bilateral, a diagnosis of a left sided hemorrhage also was made and a second operation advised. Twenty days after the first operation, a small occipitoparietal bone flap was reflected (by R Z) and a smaller

Fig 1—Schematic coronal section showing position of the hematoma between the dura and the pia arachnoid

theory explains an early small acquisition of fluid but it does not explain the gradual increase that takes place over a period of months.

The inference has been made by Putnam<sup>2</sup> that disintegration of blood in the hematoma is of prime importance, for this results in a greatly increased osmotic pressure which is responsible for drawing fluid into the sac. The observations made in the following case of bilateral subdural hematoma tend to substantiate the latter view.

REPORT OF CASE

*History*—C L, a white man aged 46, was referred to the Peter Bent Brigham Hospital Oct 19 1933, by Dr Roger Spaulding of Duxbury, Mass, for treatment of a suspected tumor of the brain. The patient had enjoyed excellent health and was active as a roof inspector until July 26 1933, when headaches occurred over the right temporal region which radiated upward toward the top of the head. There had not been any single severe cranial trauma but he had been in the habit of raising trap doors with his head while climbing up to roofs. It is likely that the later discovered intracranial hemorrhage was sustained during one of these rather insignificant injuries. The headaches increased in severity and on August 1, while on a vacation, he became confused and temporarily wandered away from his family. He returned to work, August 18, but did not feel rested. September 15 he suffered a temporary numbness and shooting pain in the left knee and had difficulty in speech for a few minutes. The headaches subsequently increased in severity but were tem-

Fig 2—Right subdural hematoma

encapsulated hematoma was removed intact from the left occipitoparietal region. The patient's postoperative course was uneventful and the euphoria promptly disappeared. He has remained symptom free six months since the last operation and has returned to work.

PATHOLOGIC STUDIES

*Right Subdural Hematoma*—Gross Examination. The specimen was a flattened, ovoid fluid-containing sac measuring 16 cm in length, 7.5 cm in maximum width, and 1.5 cm in maximum thickness (fig 2). When immersed in saline solu-

2 Putnam T J, in discussion on Gardner<sup>1</sup>

tion it displaced 120 cc of fluid. Its walls were fibrous but did not measure over a millimeter in thickness. The thin enveloping membrane and the fluid character of the cyst contents gave the sac a very flabby consistency. The flattened surface, which had been pressed against the arachnoid, was smooth and glistening. The surface that had been adjacent to the dura was somewhat dull, slightly roughened, and a little irregular in contour. The hematoma was dark red, but in a few areas there were brownish and greenish deposits of blood pigments. The hematoma fluid was thin and dark reddish

Fig 3—Left subdural hematoma

brown. It resembled dilute, partially hemolyzed and disintegrated blood. Cultures of this fluid were sterile.

**Microscopic Examination.** The membrane of the sac was composed of dense fibrous tissue which often was hyalinized. The dural side was thicker and more plentifully supplied with vessels than that which had been contiguous to the arachnoid. In some places a thin organized blood clot was found on the inner surface. The wall had occasional infiltrations of polymorphonuclear leukocytes and lymphocytes. A few macrophages contained blood pigment.

**Left Subdural Hematoma—Gross Examination.** The specimen was an ovoid, flattened hematoma measuring 9 cm in length, 4 cm in greatest width and 1.1 cm in maximum thickness (fig 3). Except for the smaller size, the general appearance was similar to the one that previously had been removed from the right side of the head. Again, the surface adjacent to the arachnoid was smooth as contrasted to the dural surface which was a little irregular and rough. The walls were less than a millimeter in thickness. Though the external surface was mostly a dark red, there were scattered mottled areas of reddish brown and green deposits of altered blood pigment. The cavity contained diluted fluid blood. Cultures of this were negative.

#### COMMENT

We believed that chemical examination of the contents of the hematoma sac might offer some explanation for the increase in size of the sac, which must have occurred to explain satisfactorily the clinical course. Determinations made on the right hematoma, in which the entire fluid including the serous portion and remaining red blood cells was used, were as follows: total protein, 8 Gm per hundred cubic centimeters, globulin, 5.1 Gm per hundred cubic centimeters, albumin, 2.9 Gm per hundred cubic centimeters, nonprotein nitrogen 31 mg per hundred cubic centimeters, and chlorine as sodium chloride, 615 mg per hundred cubic centimeters.

The total protein in normal whole blood is approximately 18.5 Gm per hundred cubic centimeters of blood. This includes the plasma protein, which consists of approximately 2.8 Gm of albumin, 0.95 Gm of globulin and 0.25 Gm of fibrinogen per hundred cubic centimeters of whole blood. The hemoglobin of the cells accounts for the additional 14.5 Gm.

The whole blood, then, which originally comprised the subdural hemorrhage had a total protein value of from 18 to 19 Gm. In contrast to this, the hematoma

sac fluid as found at operation had a total protein content of only 8 Gm. This important difference may be accounted for in two ways. First, that a portion of the encysted blood had been reduced to substances that could diffuse out of the sac and hence lessen the remaining total protein value. Second, that the contents of the sac had been diluted. Both factors may have played a part to bring about the observed changes, but it is likely that the latter process was the more important one. The reduction of the hematoma total protein figure from 18-19 Gm to 8 Gm is probably a fair indication that the blood originally in the cyst had been diluted about two and a third times, or, conversely, that the volume of the hematoma had increased to about two and a third times its initial size.

Chemical examination was subsequently made on the material removed from the left subdural hematoma. The total protein value of the whole fluid was 6 Gm per hundred cubic centimeters. It may again be inferred that dilution had taken place and the reduction from 18-19 Gm to 6 Gm of protein indicated a dilution of three times or a corresponding increase in volume of the cyst to about three times its original size.

The left sided subdural hemorrhage presumably occurred at the same time as did the right one, but it remained undisturbed in the subdural spaces for twenty days longer than the right one. Coincidental with this longer stay in the subdural space there was a greater dilution in the left sac. One therefore suspects that the fibrous wall of such a hematoma acts as semiper-

Fig 4—Apparatus employed for testing left subdural hematoma as a semipermeable membrane.

meable membrane, which permits the ingress of water and crystalloids but does not allow protein to escape.

In order to study some properties of the membrane the left hematoma sac was emptied of its contents and refilled with oxalated whole blood (by R. G.). A small bore manometer tube was tied into one end of it and the sac then immersed in a beaker of 0.9 per cent sodium chloride and 0.1 per cent sodium oxalate (fig 4). Observations over a twenty-four hour period showed

a maximum rise to 15.5 cm in the manometer tube. Frequent tests on the external fluid with 2 per cent tannic acid showed the bath to be protein free. These facts demonstrated that the membrane allowed the passage of water and sodium chloride into the sac but did not allow egress of the protein molecules.

It is shown from the preceding discussion that the hematoma wall acts as a semipermeable membrane and

Fig. 5.—Apparatus employed for comparative studies on relative osmotic pressures of nonhemolyzed blood (at left) and of hemolyzed blood (at right)

that the contents of the sacs had been diluted. In order to complete the chain of pathologic processes, the factor must be found that induces fluid to distend such a cyst many months after the original hemorrhage. It has been well known that red blood cells may remain intact for long periods of time when encysted within these hematomas. It is commonly observed that when found soon after their formation these extravasations contain practically whole blood, that after a few months many red cells have disintegrated, and that after many months most of the cells have disappeared. (A red blood cell count on the fluid from the left hematoma of

our patient showed about one fifth of the erythrocytes remaining.) In other words, there is a gradual and progressive breakdown of red cells over a long period of time. When erythrocytes disintegrate, two major processes take place which need consideration. The first, and most important, is the liberation of hemoglobin from the cell stroma. The second is the reduction of this released hemoglobin to smaller molecular protein aggregates.

Hemoglobin, when present within the red cell, has little effective osmotic tension with relation to surrounding tissue fluids. However, when hemoglobin is liberated from the limiting cell membrane it has a distinctly higher effective osmotic pressure. The following experiments were undertaken (R. G.) to demonstrate this change in effective osmotic pressure when hemoglobin is released from the red cells.

Human whole blood was treated with ovalate crystals to prevent its coagulation. Powdered sodium ovalate was added in amounts of 100 mg per hundred cubic centimeters of blood. This blood was then divided into two portions. Half of it was treated with chemically pure saponin which is a powerful hemolyzing agent even in dilutions of 1:100,000 parts of blood. A few milligrams of this material per hundred cubic centi-

meters of blood was sufficient to cause complete hemolysis in a few minutes. This small amount of added saponin had no intrinsic osmotic pressure effect, as shown by appropriate studies. The second half of the blood was not treated with saponin and was used as a control.

These two specimens of blood, one completely hemolyzed and the other normal, were placed in semipermeable membrane sacs of cellophane 600 seamless tubing. Each of these sacs was then attached to a small bore manometer tube and each was placed in a bath (fig. 5) consisting of 0.9 per cent sodium chloride and 0.1 per cent of sodium ovalate. The ovalate in the outer baths was then of the same concentration as that within the sacs and prevented coagulation of the control blood. Each piece of apparatus was maintained at room temperature. Observations showed maximum rises in the two manometer tubes within eighteen to thirty hours. Repeated experiments gave an average rise of 16.5 cm for the nonhemolyzed blood, compared with an average rise of 89 cm for the hemolyzed blood.

One might expect that there should be no rise in the manometer of the control (nonhemolyzed) blood when exposed to an essentially isotonic solution. This rise of 16.5 cm is explained by the fact that, though the blood on the inside of the sac and the fluid surrounding the sac have essentially the same osmotic pressure when examined by freezing point methods, yet when they are placed on opposite sides of a semipermeable membrane the protein is held back while the sodium chloride diffuses through and is present on both sides of the membrane in proportions that follow the law of Donnan's equilibrium.

The reduction of hemoglobin molecules, as mentioned previously, also has a considerable bearing on the subject under discussion. The molecular weight of this substance has been estimated to be at least 16,000 and by some authorities is said to be as high as 64,000. When this huge molecule breaks down, a very large number of smaller aggregates are formed, and the molecular concentration per unit of space is thereby greatly increased. Since osmotic pressure is directly proportional to the molecular concentration of a fluid, it follows that the disintegration of hemoglobin, to a certain point, is attended by an enormous rise in osmotic tension.

The following series of events represent the conditions as we believe them to occur in these subdural hemorrhages. A head injury, often so trivial that it is

Fig. 6.—Cellophane tubing sac employed to measure amount of fluid that blood absorbs by osmotic tension (when immersed in physiologic solutions)

forgotten, causes a rupture of a vein as it crosses the subdural space. A large hemorrhage then occurs and the entrapped blood is rapidly surrounded by a fibrinous wall, which is later organized to a fibrous and vascularized structure. The wall, acting as a semipermeable membrane, permits passage of fluid into the cyst to compensate for the differential osmotic tension that exists between whole blood and adjacent tissue fluids. This first stabilization occurs fairly rapidly. The encysted red cells then gradually and slowly disintegrate.

over a period of several months and this process causes a slow but great rise in the osmotic tension of the hematoma fluid, which is compensated for by the acquisition of fluid from the surrounding structures. The resulting late increase in volume of the hematoma causes late onset of symptoms by direct pressure on the adjacent brain and by increasing the general intracranial tension.

The following experiments were undertaken in order to gain some idea of the amount of fluid that blood might take up by osmotic tension.

About 1 cc of oxalated whole blood was placed in a cellophane sac and the ends were sealed (fig 6). This sac was then placed in a bath of 0.9 per cent sodium chloride and 0.1 per cent sodium oxalate. Weights were made of (1) the sac (2) the sac plus the blood (3) the sac and its contents after immersion in the bath for from twenty-four to thirty-six hours. When nonhemolyzed blood was employed there was an average of 90 per cent increase in weight of the blood after the immersion. When (saponin treated) hemolyzed blood was placed in such a sac and subjected to the same immersion, the increase in weight averaged 230 per cent (final fluid weight was three and a third times that of original blood weight).

From these observations it seems reasonable that subdural hematomas may in a similar manner increase to two or three times their original volume.

Gardner stated that the fluid which entered the subdural hematoma was derived from the surrounding tissues and particularly the cerebrospinal fluid. It would seem likely, however, that the added substance may come in part from the plasma of the circulating blood. As has often been noted, there is a rich vascular capillary system within the walls of the hematoma sac. By microscopic examination, many of these vessels are seen to lie very close to the lumen of the cyst and conditions appear to be favorable for an exchange of fluid between these capillaries and the contents of the sac. It would appear more logical for the necessary fluid to come from these capillaries rather than from the arachnoid spaces by traversing the arachnoid and the hematoma sac wall. Ordinarily the cerebrospinal fluid does not pass through the arachnoid into the subdural space. The effect of a close approximation of a hematoma sac to the external surface of the arachnoid is unknown, but it is not necessary to draw upon an unknown factor for a ready means for exchange of fluids, namely, from the capillary networks of the hematoma wall.

#### SUMMARY AND CONCLUSIONS

Evidence is presented from clinical and experimental observations made from a case of bilateral subdural hematoma that (1) the wall of a subdural hematoma acts as a semipermeable membrane, (2) blood within a subdural hematoma breaks down slowly over a period of months, (3) disintegration of blood produces a great rise in its effective osmotic pressure, and (4) blood within a subdural hematoma is progressively diluted.

It is believed that progressive liberation of hemoglobin from the erythrocyte stroma and subsequent disintegration of the hemoglobin molecule increase the osmotic tension in a hematoma sac over a period of months and that fluid is therefore gradually drawn in from the surrounding structures. The resultant augmentation in size of the lesion causes rising intracranial pressure and progression of clinical symptoms. The late onset of symptoms is therefore directly dependent on the slow disintegration of red blood cells encapsulated within the hematoma membrane.

## AGRANULOCYTIC ANGINA FOLLOWING INGESTION OF DINITROPHENOL

S. STEPHEN BOHN, MD

ANN ARBOR, MICH

During recent months the medical literature has been characterized by numerous reports of cases illustrating unfavorable reactions and deaths following the use of dinitrophenol, the barbiturates and amidopyrine. In the instances of these reactions following therapy with the barbiturates and amidopyrine, several observers have cited a resulting neutropenia or agranulocytic angina. There is reference made, however, to only one case of agranulocytic angina following the ingestion of dinitrophenol.<sup>1</sup> The report includes a case in which agranulocytosis developed after the ingestion of dinitrophenol over a period of two weeks, the patient recovering following treatment. Since no mention was made in this case regarding the amount of the drug taken during the two weeks or of the blood picture, and since in no other report of dinitrophenol poisoning has there been reference made to an ensuing neutropenia (those reports including a blood picture showed essentially normal white blood counts, while the remaining reports did not include any data concerning the white blood cells), a case of agranulocytic angina following the ingestion of dinitrophenol is here submitted.

#### REPORT OF CASE

**History**—C. P., a Jewish girl, aged 19 years, single, a stenographer, who entered St. Joseph's Mercy Hospital, May 4, 1934, complained of a severe sore throat, hoarseness and dysphagia. She was brought into the hospital by her physician, Dr. F. L. Arner, who stated that she had been taking "Nitraphen" (the sodium salt of 2, 4 dinitrophenol) in order to reduce her weight. The following history was then obtained.

Eighteen months before admission her weight had been 181 pounds (82.3 Kg.), this being the most she had ever weighed. At that time she was 18 years of age. She went on a diet and experienced a progressive loss of weight to 162 pounds (73.6 Kg.) within eight months. Her weight fluctuated about this point till four months before admission, when she states that a relative informed her of a person who had been taking dinitrophenol and had lost weight without ill effects. She was also told that this person's physician had "analyzed" the drug, found it to be "all right" and was himself using it in order to lose weight. Our patient bought a bottle of "Nitraphen" containing fifty capsules, each capsule containing 100 mg (0.1 Gm) of 2, 4 dinitrophenol sodium. She did not seek a physician's advice nor did she ask the druggist from whom she bought the drug regarding the dosage. The label on the bottle stated "The usual dosage—1 to 3 capsules per day, taken with meals and after a week's interval increase medication as necessary until a weight loss of 2 or 3 pounds weekly is produced. Three capsules per day will usually produce an average weight loss of 2 or 3 pounds weekly." There was on the label a reference to THE JOURNAL.<sup>2</sup>

Her weight at this time was 166 pounds (74.5 Kg.), and she started by taking one capsule three times a day following meals for the first two weeks. The dosage was then increased to twice that amount for a week but with no loss in weight. She began to menstruate and, feeling quite miserable, stopped taking the drug. With the completion of her period she resumed the ingestion of two capsules three times a day for two weeks but began to perspire freely, feeling warm even in cold weather and still with no loss in weight. She stopped medication and resumed its ingestion as before in two weeks. She perspired continuously, even while scantily clothed in cold

From St. Joseph's Mercy Hospital.

weather. She felt tired but attributed this to the fact that she was working hard in her office. After ten weeks of medication in this manner she contracted a cold and at the same time noticed a rash on the neck, chest and anterior surfaces of the arms. The rash was a maculopapular eruption and was quite pruritic. She did not go to a physician but stopped the drug and applied an alcohol rub, which relieved the itching. Several days later she noticed a patch on her left shoulder and one on her right arm, these patches being covered with what she termed "blood blisters." She felt warm, but since her temperature was not determined with a thermometer the degree of fever could not be ascertained.

All these symptoms eventually disappeared and six weeks before admission she again started using 2, 4 dinitrophenol sodium as before. In ten days she again experienced a pruritic macular eruption on the chest and neck, as well as "blood blisters" beneath her breasts. She felt extremely warm and complained of a sore throat. Stopping the drug and visiting a physician, she was told that she had a streptococcal sore throat and therapy was instituted in the form of bed rest for two days, gargles, swabbing of the throat and the taking of

had no appetite. She became very hoarse, could not swallow solids and had a fever of 104 F. The hoarseness increased until she could only whisper. The menses stopped two days before her admission, but the hoarseness, temperature, dysphagia and soreness of the throat became progressively worse until she was admitted, at which time she weighed 154 pounds (70 Kg). She had stopped the use of 2, 4 dinitrophenol sodium four days previously.

There was nothing significant in the past history, and there was no history of allergy.

**Physical Examination**—At examination the patient was slightly overweight, she perspired freely and had a temperature of 104.4 F. She was very hoarse, speaking only in a whisper and having difficulty in opening her mouth wide. There was some cyanosis about the lips, but no rashes. The patient was oriented and answered questions intelligently but dozed off easily. The remainder of the general examination was not significant. The blood pressure and a basal metabolic rate were not taken. The heart and lungs were normal. The patient was referred to Dr. A. C. Furstenberg, professor of otolaryngology, University of Michigan, who submitted the following report:

"On admission to the hospital the patient's throat gave the following appearance. Both tonsils were covered with a white membrane. It was diffuse and extended on to both pillars on both sides. The spread of the membrane was not unlike that of diphtheria, although its color was not characteristic of a Klebs-Loeffler infection. There was marked hyperemia of the pillars, soft palate and posterior wall of the pharynx. Because of the extensive inflammatory process, together with marked prostration of the patient, a tentative diagnosis of agranulocytic angina was made.

"Forty-eight hours following admission a rather extensive ulceration occurred within the upper pole of the right tonsil and the adjacent pillars and soft palate. This ulceration was large enough to admit the index finger in the region of the supratonsillar fossa. It involved considerable of the soft palate in this region. There was a similar ulceration on the left side, only it was considerably smaller."

**Laboratory Examination**—Examination of the urine showed albumin, three plus. The sediment was loaded with granular casts and contained from fifteen to twenty pus cells per high power field.

A blood count revealed hemoglobin, 103 per cent (Sahl), red blood cells, 4,860,000 per cubic millimeter, white blood cells, 1,150 per cubic millimeter. In the differential count fifty cells were counted, of which forty were lymphocytes and ten were large mononuclear leukocytes.

A smear from the throat showed mixed bacterial flora, culture of the throat smear showed mixed staphylococci and streptococci but no Klebs-Loeffler bacilli.

The Kahn test of the blood was negative.

**Progress in the Hospital**—For three days the patient was given hot saline throat irrigations, powdered acetylsalicylic acid to the back of the tongue and an ice collar about the neck. An attempt was made to force fluids by mouth at the beginning. Twenty cubic centimeters of pentnucleotide was given twice daily, intramuscularly for four days, 30 cc on the fifth day and 10 cc on the sixth day. On the second hospital day a blood transfusion of 250 cc of whole blood was given as well as an intravenous infusion of 500 cc of 5 per cent dextrose. On the third day 1,000 cc of physiologic solution of sodium chloride was given subcutaneously, and when the patient became irrational morphine sulphate one-fourth grain (0.016 Gm.), was given hypodermically. Late that evening she became quite restless. The temperature was 100 F, respirations were 20 per minute and the pulse was 90 per minute but irregular. She was given digifolm and then put into an oxygen tent, following which the cyanosis decreased, her respirations became easier and she took more fluids by mouth.

May 7, the blood pressure was 112 systolic and 72 diastolic. She received 100 cc of 50 per cent dextrose intravenously. On this day she was seen by Dr. Raphael Isaacs of the Simpson Memorial Institute, University of Michigan, who reported the following: "Red blood cells, 4,240,000 per cubic millimeter, white blood cells, 5,500 per cubic millimeter, hemoglobin, 88

Clinical course in case of agranulocytic angina following ingestion of 2, 4 dinitrophenol sodium

some white pills. She then noticed a red and slightly pruritic rash along the anterior surfaces of both legs. On getting out of bed at one time she felt dizzy and fainted. Occasionally she became nauseated but did not vomit.

By this time she had taken the contents of four bottles of "Nitra-phen." On purchasing the fifth bottle ten days before admission she again started ingestion of the drug as before until eighteen capsules had been taken, when she experienced another onset of the menses, this one coming on two weeks early. (Her previous menstrual periods had been essentially normal, coming on about once a month, although rarely she was one week early or one week late but not during the past four months. The menses usually extended over a period of two days and were characterized by cramps, headaches, dizziness and some fatigue, but no bed rest was ever required.) This menstrual period had its onset four days before her admission and was associated with a sore throat, headache and fever. Her weight was 158 pounds (71.8 Kg). She went on a picnic that night but was forced to come home early. She was worse the following morning and went to her physician, who gave her some pills, swabbed her throat and advised gargles. She returned to bed, became worse that night and

per cent (Sahl), polymorphonuclears (neutrophil), metamyelocytes and immature forms, 52 per cent, large lymphocytes, 6 per cent, small lymphocytes, 31 per cent, monocytes, 11 per cent, eosinophils, 0. There was an extreme degree of basophilia of the granules of the polymorphonuclears, suggesting septicemia. Platelets were increased in number. The red blood cells were essentially normal. There was marked rouleau formation. The impression was that the condition as seen was the recovery phase in malignant neutropenia with septicemia."

The urine showed decreasing amounts of albumin, pus cells and casts till the specimens were normal after one week of treatment.

The data in the accompanying table concern the white blood cells during treatment.

White Blood Cells During Treatment

Date	White Blood Cells per C. Mm	Percentage of Adult Polymorphonuclear Neutrophils
May 4 (day of admission)	1 150	0
May 5	1 000	5
May 6 (a. m.)	3 550	5
May 6 (p. m.)	3 900	4
May 7	4 400	6
May 8	12 700	5
May 9	16 700	12
May 10	25 400	28
May 11	21 150	25
May 13	13 700	44

Dr Furstenberg's final report was that during convalescence these ulcers healed very slowly, and when the patient was discharged from the hospital the membrane had entirely disappeared but that there was still a small ulceration on the right side. Thus, however, was clean and appeared to be healing slowly but satisfactorily.

Since the patient was known to have taken other drugs, an effort was made to ascertain their relation to her illness. The only drugs she had taken recently were "anacin" (acetphenetidin, an acetanilid derivative with acetylsalicylic acid quinine and caffeine), acetylsalicylic acid and 2, 4 (dinitrophenol sodium). She usually took one or two tablets of "anacin" during her menstrual periods in order to obtain relief from the cramplike pains but stated that the last time she used this drug was during her menstrual period six weeks before admission. She discontinued this drug because she found that acetylsalicylic acid gave her almost as much relief, and she has been in the habit of taking from 5 to 10 grains (0.32 to 0.65 Gm.) during the menses. Since acetylsalicylic acid was used freely during the treatment and the patient made a good recovery it may be assumed that this drug probably had no etiologic bearing concerning the neutropenia.

All indications thus point toward 2, 4 dinitrophenol sodium as being the only drug responsible for her illness. Over a period of four months she took 21 800 mg (21.8 Gm.), usually starting by taking one capsule (0.1 Gm.) three times a day for two weeks and then doubling the dosage for one or two weeks. She would then experience unfavorable reactions such as a feeling of warmth, perspiration, fatigue, sore throat, vertigo and a pruritic maculopapular eruption of the skin. The blood pressure was not taken. When the ingestion of the drug was stopped, these symptoms would disappear within two or three weeks but would recur when the process was repeated. There was no yellowish discoloration of the skin, as has been reported by some observers.

It is significant to note that, by dieting the patient was safely able to lose 19 pounds (8.6 Kg.) within eight months while she lost only 12 pounds (5.4 Kg.) over a period of four months, during which time she took a total of 21.8 Gm. of 2, 4 dinitrophenol sodium and which resulted in an extreme neutropenia. During this period of four months she did not adhere to rigid dietary reduction measures but made an attempt to

exclude only fattening foods. It is also significant that the initial dosage in this case corresponded to that advised by Cutting.<sup>3</sup> Weighing 75 Kg. four months before and starting with a dosage of 300 mg (0.3 Gm.) a day, she was ingesting 4 mg per kilogram of body weight daily for the first two weeks and then increased this to 8 mg per kilogram of body weight daily till the unfavorable reactions appeared, usually within two weeks following the increase in dosage. Cutting<sup>3</sup> stated that in his eight cases single doses of from 3 to 5 mg per kilogram of body weight increased the basal metabolic rate from 20 to 30 per cent in the first hour and that this level was maintained for twenty-four hours. None of his patients noticed unfavorable reactions with this dosage but they did lose weight. He also stated that single doses of between 5 and 10 mg per kilogram caused copious perspiration and that 10 mg per kilogram three times a day was too dangerous. Our patient experienced no loss of weight even with 8 mg per kilogram of body weight until extremely unfavorable reactions, including neutropenia, had been produced.

#### SUMMARY

1. Agranulocytic angina developed in a patient after the ingestion of 21.8 Gm. of 2, 4 dinitrophenol sodium over a period of four months.

2. The dosage was 4 mg per kilogram of body weight daily for two weeks and then doubled until the onset of unfavorable reactions.

3. Treatment consisted of discontinuing the drug, administration of pentnucleotide and one transfusion of 250 cc. of whole blood, following which the patient recovered.

## UNDULANT FEVER MENINGITIS

### REPORT OF CASE WITH RECOVERY

G. A. HARTLEY, MD

G. S. MILLICE, MD

BATTLE CREEK, IOWA

AND

PAUL H. JORDAN, MD

HARTFORD, CONN.

The patient with proved undulant fever meningoencephalitis who formed the subject of a report by Sanders<sup>1</sup> in September 1931 died in the University Hospital at Iowa City, Nov. 3, 1931. The case has since been reported with postmortem observations by Hansmann and Schencken.<sup>2</sup> Incidentally, the case is the first reported proved occurrence of a meningeal infection in man with the porcine variety of *Brucella melitensis*. While proved infections of the human meninges by organisms of the *Brucella* group are rare, the recovery from such an infection is still more uncommon. The present case report should therefore be of especial interest, particularly from the standpoint of therapy.

#### REPORT OF CASE

*Epidemiology*—About March 12, 1931, L. M., with four other men was dehorning a herd of feeding cattle which had been recently received from various shipping centers. Nothing is known about abortions occurring before or since in that

3. Cutting, W. C., Mehrtens, H. G. and Tainter, M. L. Actions and Uses of Dinitrophenol. J. A. M. A. 101: 193 (July 15) 1933. From the Battle Creek Hospital, Battle Creek, Iowa.

1. Sanders, W. E. Undulant Fever Meningitis. Organism in Spinal Fluid. J. Iowa M. Soc. 21: 50 (Sept.) 1931.

2. Hansmann, C. H. and Schencken, J. R. Melitensis Meningoencephalitis. Mycotic Aneurysm Due to *Brucella melitensis* Var. Por. Am. J. Path. 8: 435 (July) 1932.

stock. The other four men were not ill subsequently. About the same time, the patient alone skinned two ewe sheep which had died supposedly following injuries produced by dogs. There was an unusual amount of serum beneath the skin of the animals, and ecchymoses about the back were present. Another ewe aborted two lambs at that time but lived. In the fall of 1931, one brood sow on the place aborted her litter.

*History*—L. M., a white American male farmer, aged 35 was brought to the Battle Creek (Iowa) Hospital, April 7, 1931, complaining of intermittent fever, daily chills, throbbing right parietal and temporal headache, rash over the hands and arms, stiffness of the ankles, and increased constipation during a period of nineteen days. The family history was irrelevant. The past history was also irrelevant except for the presence of a severe sore throat with slight hemoptysis at times, which began three weeks prior to and merged with the present illness. The patient had always been slightly costive.

March 19 the patient became suddenly ill with a severe shaking chill followed by fever and accompanied by a severe throbbing right parietal and temporal headache. An erythematous rash over the hands and arms together with some slight pain, swelling and stiffness in both ankles occurred within the first forty-eight hours. The temperature March 22, was 103 F orally. From the onset until the administration of the second dose of the toxic filtrate, April 23 there were daily chills preceded by fever and followed by profuse diaphoresis. The daily fever at first began in the afternoon, but later in the course it occurred in the morning with the daily duration of the hyperpyrexia tending to increase. The headache, always a prominent symptom, subsided somewhat prior to hospitalization but returned almost immediately afterward. The patient was confined to bed from the onset. He had always been somewhat costive but this condition became much more marked while he was ill, requiring daily laxatives or enemas. He lost much weight, although the exact amount is not known. Prior to hospitalization, a definite diagnosis had not been established.

*Course in Hospital*—On admission to the hospital the patient's temperature was of 101 F rectally. The only significant physical finding, aside from the erythematous rash over both upper extremities and the stiffness of the ankles, was a quite definite enlargement of the spleen. Until April 21, treatment was chiefly symptomatic and supportive together with the use of a total of three intramuscular injections of a nonspecific foreign protein, which resulted in essentially no improvement. For the first ten days of hospitalization the temperature ranged from normal or slightly above to 103 to 104 F rectally the same day, the maximum elevation occurring at no regular period in the day. The patient's consciousness was somewhat clouded after the first three or four days of hospitalization but on the night of April 16 (exactly four weeks from the onset of the illness) he was probably more noisy than usual, and the following morning he complained of a stiff neck. The usual physical and cerebrospinal fluid signs of a meningitis were present.

Special therapy with a toxic filtrate of a culture of certain members of the *Brucella* group was begun April 21, two injections of 0.5 cc each being given on that date, the first subcutaneously and succeeding ones intramuscularly. A third injection of 1 cc was given two days later, with the result that for the first time the temperature was normal for an entire day and remained normal. The injections were followed by local induration and erythema, but no necrosis or abscess formation occurred. The other therapy consisted aside from symptomatic and supportive measures, of repeated lumbar punctures, with the withdrawal of sufficient amounts of cerebrospinal fluid to bring the pressure to normal as much as 60 cc being obtained at times. Each withdrawal of fluid was followed by quite definite symptomatic relief. A total of eight such lumbar punctures were done from April 17 to April 24 inclusive, and following the administration of the toxic filtrate the spinal fluid cell count steadily decreased until it was normal (below 6 cells) April 24. However, the irrationality and disorientation continued and on May 5 another intramuscular injection of 1 cc of the toxic filtrate was given. Periods of rationality began on May 10 but a normal mental status was not obtained until eleven days later, and even then there was

occasional involuntary micturition for several days. The patient was discharged from the hospital mentally normal, although much weakened physically, May 24. There had been no convulsions at any time.

*Subsequent Course*—The patient was again seen on Nov 14 1931, and stated that for two months after hospitalization there was considerable swelling of the feet and ankles whenever he was up and about. June 6 he weighed 118 pounds (53.5 Kg) and gained 18 pounds (8 Kg) in the next three weeks. His weight, November 14, was 140 pounds (63.5 Kg). There had been no chills, fever, headaches, joint pains, nervous manifestations or persistent constipation since his discharge. He did not do much work until September because of some residual fatigability but since then had been able to do the usual work about the farm except when hindered by a neuralgia in the interscapular area, which had been present intermittently for several years. Physical examination, November 14, was essentially negative and a blood specimen drawn at that time did not agglutinate *Brucella melitensis*.

*Laboratory Examinations*—Dr. A. V. Hardy, Dr. I. H. Borts and Thelma Decapito, all of the Iowa State Hygienic Laboratories at Iowa City, performed the serologic and bacteriologic studies. Dr. Hardy suggested the use of the toxic filtrate of a culture of members of the *Brucella* group and furnished the material.

*Serology*—Blood drawn for multiple agglutination tests was reported, April 10, as being positive for *Brucella melitensis* in a dilution of 1:80 and the same results were obtained on another specimen nine days later. Blood drawn on May 21 gave negative agglutination reactions but had been delayed in transit. A blood specimen obtained November 14 (about six months after the discharge of the patient from the hospital) was also reported as showing negative agglutination reactions for *Brucella melitensis* and had been received in good condition. A specimen of cerebrospinal fluid received at the laboratory, May 23 was reported as not agglutinating *Brucella melitensis* in any dilution.

*Bacteriology*—Two guinea-pigs inoculated with fresh blood April 24, proved to be negative on autopsy at the end of a month, while two other guinea-pigs inoculated with freshly drawn cerebrospinal fluid on the same day showed the usual changes in the liver, lymph nodes and spleen for a *melitensis* infection on autopsy, and cultures obtained from the tissues were reported on July 8 as growing the porcine variety of *Brucella melitensis*. A blood culture drawn on April 29 was also negative. The cerebrospinal fluid taken on two occasions during the acute stage of the meningitis was cultivated on ascitic fluid blood agar and chocolate agar and was reported as showing no growth after four days.

*Cerebrospinal Fluid*—The first specimen of cerebrospinal fluid, drawn on April 18, the day following the onset of the meningitis, was turbid and under increased pressure but a cell count was not made. A specimen obtained the following day contained 707 cells, with 343 polymorphonuclears and 364 mononuclears. April 20 the spinal fluid cell count was 2,280 with 1,800 polymorphonuclears and 480 mononuclears, and the fluid was distinctly purulent in character. Smears on both occasions were negative. April 24 the fluid was clear and under normal pressure, and the cell count was below 6 cells.

*Blood and Urine*—On admission to the hospital the white blood cell count was 9,000. A differential count was not made. Urinalysis was negative except for the presence of a trace to one plus albumin during the acute phase of the illness. The urine was not examined bacteriologically.

*Summary*—In a case of proved human undulant fever meningitis, with recovery the onset of the meningitis was acute and was preceded for four weeks by symptoms that could have been due to a low grade encephalitis. The blood serum obtained one week before the onset of the actual meningitis agglutinated *Brucella melitensis* in a dilution of 1:80. The cerebrospinal fluid presented a relatively high cell count with a large percentage of mononuclear cells although the percentage of mononuclear cells tended to decrease later in the course. Repeated lumbar punctures seemed to produce distinct symptomatic improvement. A toxic filtrate of a culture of organisms of the *Brucella* group injected repeatedly intramuscularly and subcutaneously relatively early in the course of

the meningitis, was followed by definite clinical improvement and recovery. The porcine variety of *Brucella melitensis* was obtained from the cerebrospinal fluid on guinea-pig inoculation but was not obtained on direct culture.

#### COMMENT

Certain interesting comparisons can be drawn between the case reported by Sanders and by Hansmann and Schencken and this one. In both instances the actual onset of the meningitis was preceded by symptoms that could possibly have been due to a low grade encephalitis. In the first case they existed probably for nine months, and in this one less than a month. In the former case the changes seen at necropsy would lead one to believe that invasion of the meninges took place by way of the blood stream. In view of the daily chills, rash and other associated symptoms in this case, a preceding bacteremia would be strongly suspected, although not proved by blood culture or guinea-pig inoculation. In both instances the actual onset of the meningitis was acute. In both instances the initial cerebrospinal fluid cell counts were relatively high, and there were more mononuclear cells than one would expect with a meningitis due to the meningococcus or one of the pyogenic organisms. In the former case, immunologic agents derived from the *Brucella* group were used rather late (over three months) in the course of the illness and the results were not so gratifying, while in this case the medication was used relatively early. In both cases, lumbar puncture produced symptomatic relief. The causative organism was isolated from the cerebrospinal fluid in both instances by guinea-pig inoculation and was of the porcine variety.

#### CONCLUSIONS

Although meager, present knowledge of undulant fever meningitis would seem to justify the drawing of certain conclusions, which may be of future value to the clinician.

- 1 A meningitis occurring in the course of proved or suspected undulant fever, and showing a relatively high cerebrospinal fluid cell count with originally a large proportion of mononuclear cells, should probably be considered—in regard to therapeutics—to be due to an infection by some organism of the *Brucella* group.

- 2 The parenteral administration of a toxic filtrate of cultures of various members of the *Brucella* group of organisms, repeated at relatively brief intervals (twenty-four hours or less), seemed to be responsible for the clinical improvement that was obtained after the third injection, and the recovery that followed the fourth treatment.

- 3 Repeated, frequent and copious drainage of the cerebrospinal fluid seems to be an important part in the treatment of the condition.

- 4 The fact that, following recovery, the blood serum fails to agglutinate the *Brucella* group of organisms does not disprove the previous presence of a meningitis due to some member of that group.

- 5 It would seem that the causative organism in an undulant fever meningitis is most surely isolated through the inoculation of freshly drawn cerebrospinal fluid into guinea-pigs, with appropriate cultures of the involved tissues when the animals have developed the pathologic manifestations of the disease in the lymph nodes, liver and spleen.

- 6 An undulant fever meningitis is a relatively rare but serious complication of undulant fever, although not necessarily fatal.

## Clinical Notes, Suggestions and New Instruments

### CAN SENSITIVITY TO DINITROPHENOL BE DETERMINED BY SKIN TESTS?

EDWARD MATZGER M.D., SAN FRANCISCO

The study here reported was undertaken to determine whether it is possible by the use of the available methods of skin testing to anticipate the skin eruptions and other signs of hypersensitivity that not infrequently occur with the therapeutic use of dinitrophenol. Without consideration of the controversial subjects of allergy, atopy or anaphylaxis and without referring to the none too clear conceptions of antigen antibody reactions as applied to nonprotein substances, I wish to submit the results of my experiment.

#### METHODS

The three possible methods of skin testing were employed for the direct test, and the intradermal method alone was used for the indirect test.

- 1 *The Patch Test*—Ten milligrams of sodium dinitrophenol powder<sup>1</sup> was placed on the flexor surface of the forearm or of the back and covered with waxed paper, held in position with a wide strip of adhesive plaster. Readings of the reactions were recorded at intervals of twenty-four, forty-eight, seventy-two and ninety-six hours.

- 2 *The Scratch Test*—Two milligrams of sodium dinitrophenol with salt solution or 2 drops of a 2 per cent aqueous solution of sodium dinitrophenol was rubbed in a scarification one-quarter inch in length made in the skin of the forearm or back. Readings of the reactions were recorded after intervals of five minutes, fifteen minutes and twenty-four hours.

- 3 *The Intradermal Test*—From 0.02 to 0.01 cc. of an aqueous solution of sodium dinitrophenol in dilutions of 1 per cent, 0.1 per cent, 0.01 per cent and 0.001 per cent were introduced intradermally in the upper arm. Readings of reactions were recorded after periods of five minutes, fifteen minutes and twenty-four hours.

- 4 *The Indirect or Passive Transfer Test*—This was carried out by the method of Prausnitz-Kustner. Blood serum from a patient with a violent clinical reaction to dinitrophenol was introduced intradermally in nonallergic individuals. Twenty-four hours later, the sites of passive transfer were tested intradermally with sodium dinitrophenol. Readings of the reactions were recorded after intervals of five minutes, fifteen minutes and twenty-four hours.

#### RESULTS

The tests were made on 157 persons, of whom 117 were patients with hay fever, asthma or urticaria, and forty had no allergic complaints. The ages varied from 6 to 63 years, and there were 103 males and 54 females.

The three direct tests on each one of these 157 allergic and nonallergic individuals were entirely negative and hence gave no indication of skin sensitiveness to the drug.

Another patient suffered a severe skin reaction during a period of self medication with dinitrophenol. She was not tested directly for skin sensitivity at the time because there was no normal skin available. Therefore, the indirect test of passive transfer was applied. Her blood serum was injected into the skin of three normal individuals. Later these injected areas were tested directly by the intradermal method. There were no positive reactions in any of the three individuals, and hence the results were entirely negative.

Twelve individuals were given therapeutic doses of sodium dinitrophenol by mouth. Four of the number were allergic as shown by the presence of hay fever, asthma or urticaria. In three of the twelve, including one of the four allergic individuals, a definite urticarial eruption developed during which the drug was temporarily discontinued. These three individuals were given the drug again in the same or even larger doses and as yet have had no further difficulty.

<sup>1</sup> The sodium dinitrophenol used in these experiments was kindly furnished by Dr. M. L. Tainter.

The skin tests in these reacting individuals were entirely negative. Certainly, if the skin eruptions were truly allergic, repeated contacts and reexposures should lead to increasingly severe reactions. This does not seem to be the case.

Recently a single instance was reported of a passive transfer test with dinitrophenol giving positive results.<sup>2</sup> This is not in accord with my experiences.

#### CONCLUSIONS

1 Entirely negative results were obtained in tests for skin sensitivity to sodium dinitrophenol by means of the patch, scratch and intradermal methods in 157 individuals.

2 Three of these patients later showed a skin reaction to the therapeutic use of dinitrophenol.

3 In a patient who showed a severe skin reaction to dinitrophenol, passive transfer of sensitivity could not be demonstrated.

4 These results indicate that skin tests will be of no value in predicting skin sensitivity to dinitrophenol.

#### DINITROPHENOL POISONING CAUSING JAUNDICE REPORT OF CASE

NATHAN SIDEL, M.D., BOSTON

Within the past year, dinitrophenol has been used extensively as a means of reducing weight. However, its possible harmful effects have not been realized sufficiently until very recently. In papers by Anderson, Reed and Emerson,<sup>1</sup> Geiger,<sup>2</sup> Poole and Haining,<sup>3</sup> and Tainter and Wood,<sup>4</sup> fatal results from the use of dinitrophenol have been reported. In all probability a great many more poisonings and fatalities have occurred, since many druggists are dispensing dinitrophenol without a physician's prescription, under both the name of dinitrophenol and various proprietary names. A case of toxic hepatitis with intense jaundice following the use of dinitrophenol is here reported.

#### REPORT OF CASE

B. R., a white woman, unmarried, aged 26 had used various reducing diets because she weighed too much for her stature (58 inches, 145 cm). The past history and family history were essentially negative. The patient began taking dinitrophenol, Feb. 18, 1934 under a physician's direction. The exact dosage could not be determined but it was probably 1½ grains (100 mg.) four times a day. After a period of fourteen days she began to feel tired and had slight cramplike pains in the epigastrium. The drug was stopped at this time, the patient had lost 10 pounds (4.5 Kg.) in the two weeks. The following morning, March 7, there was severe urticaria and pruritus involving the legs and feet. The patient states that the itching was "terrific" and the urticaria appeared in the form of "large welts." Within the next twenty-four hours the entire body was involved, and the condition lasted four days. March 12, the day following the disappearance of the urticaria, a definite yellow tinge of the sclerae was observed by friends, and definite jaundice developed within the next few days. The stools were clay colored and the urine was dark brown, also, there was marked anorexia and the patient was very listless.

I saw the patient, March 20. She was poorly developed but well nourished, with marked jaundice but there was no distress. The temperature was 98 F and the pulse rate was 84. The upper part of the abdomen was somewhat prominent and a definitely tender, smooth liver edge was palpable about 5 cm. below the right costal margin. The upper border of liver dullness was in the right fourth interspace. The spleen was not palpable and there was no skin eruption. A diagnosis of toxic hepatitis caused by dinitrophenol was made.

Several urine examinations were negative for sugar but showed varying amounts of albumin, a specific gravity of from

1004 to 1014 and many pus cells but no casts or red blood cells. The test for bile in the urine was strongly positive. The stool was clay colored until April 4, at which time pigment was present. The blood showed hemoglobin, 80 per cent (Sahli), red blood corpuscles, 5,250,000, white blood corpuscles, from 14,400 to 6,600. The blood smear was normal. The blood chemistry showed blood sugar, 95 mg., nonprotein nitrogen, 27 mg., and cholesterol, 168 mg. The icteric index at the height of jaundice was between 100 and 80 and the van den Bergh reaction was between 10.8 and 9.0. With bed rest for one month and a diet high in carbohydrate and low in fat supplemented by 10 units of insulin before meals and sodium phosphate each morning the strength and appetite of the patient gradually improved. There has been a gradual reduction in the jaundice, although she still presents some icterus after nine weeks. The liver has decreased in size so that it is barely palpable, the tenderness of the liver edge has practically disappeared.

#### SUMMARY

A woman, aged 26, took approximately 360 mg. of dinitrophenol daily for two weeks. Urticaria with pruritus developed and subsequently intense jaundice, an enlarged tender liver and clay-colored stools. Gradual improvement is taking place, although she has been jaundiced nine weeks to date.

### Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY OF THE AMERICAN MEDICAL ASSOCIATION HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT  
H. A. CARTER, Secretary

#### SOURCES OF ULTRAVIOLET AND INFRARED RADIATION USED IN THERAPY

##### PHYSICAL CHARACTERISTICS

W. W. COBLENTZ, Ph.D., D.Sc.  
WASHINGTON, D. C.

(Concluded from page 188)

8 *The Quartz Mercury Arc*—The radiation from the quartz mercury arc lamp is emitted principally in a series of intense spectral lines (charts 2 and 6) superposed on a faint continuous spectrum that contributes but little to the total ultraviolet emanating from the arc.

Recently a number of new types of mercury arc lamps have been put on the market. They serve two purposes: (1) those emitting a high ultraviolet intensity, for therapeutic purposes, and (2) the so-called sunlamps, usually emitting a low ultraviolet intensity, requiring long exposures, sold to the public for home use without the supervision of an experienced physician.

*The Hot Quartz Lamp*—The earliest and best known type of quartz mercury arc lamp (the so-called hot quartz lamp) operates at a high vapor pressure and a relatively high temperature. The current through the lamp is fairly large (from 3 to 4 amperes) and the voltage on the burner is low (from 65 to 70 volts).

Investigations<sup>6</sup> of quartz mercury arc lamps having (1) a solid tungsten anode and (2) a liquid mercury anode show that there is no appreciable difference in the ultraviolet component radiation emitted by these two types of lamps when operated on the same energy input in the burner. Air-cooled burners operated on alternating current (through the burner) and water-

cooled burners operated on direct current appear to have a somewhat higher ultraviolet radiation component than air-cooled, direct-current burners, owing to the lower temperature of the lamp.

Aside from several strong emission lines in the region of 10,000 to 12,000 angstroms, the quartz mercury arc emits but little infra-red radiation. The infra-red rays that are emitted emanate principally from the incandescent tungsten anode and especially (in both types of lamps) from the quartz enclosure and the hood, which emit low temperature, long wavelength, nonpenetrating radiation.

Physically there is no comparison between this type of radiation and that of the sun (chart 7), and it is hardly to be expected that these two sources will give the same results in all types of light treatment, and in dye fading.

In chart 7 is given the spectral energy distribution (unshaded vertical lines) of a 110-volt vertical Uviarc lamp operated on 65 volts, and about 4 amperes in the burner. Owing to the high current density, the temperature and the pressure are relatively high, and the resonance emission line at 2,537 angstroms is practically of the same intensity as the lines at 3,020 and 3,130 angstroms, in contrast with the so-called cold quartz vapor glow lamp (chart 7), in which the line at 2,537 angstroms contains over 95 per cent of the radiation emitted by these three lines.

**The Mazda Sunlight Lamps** A recent production (The Mazda S-1 and the Mazda S-2 "sunlight" lamps) is a combination of an incandescent tungsten filament and an arc in mercury vapor between highly incandescent electrodes of tungsten. This is accomplished by operating a V-shaped helical tungsten filament in parallel with the mercury arc, but it is at a considerably lower temperature than the incandescent tungsten electrodes forming the arc at the top of the V-shaped filament. The surrounding globe, of special glass absorbs the rays of wavelengths shorter than 2,800 angstroms which are not present in sunlight. The mercury arc supplements the ultraviolet radiation, which is only feebly emitted by the incandescent tungsten electrodes at from 2,800 to 3,650 angstroms.

The result of this combination of incandescent solid and arc-vapor radiation is an unusual emission spectrum consisting of a series of strong ultraviolet emission lines of mercury vapor (at 2,800, 2,967, 3,020, 3,130, 3,340, 3,650 and 4,050 angstroms, chart 6), superposed on a continuous spectrum radiation from the incandescent solid, which increases rapidly in intensity (beginning to be perceptible at about 3,650 angstroms) and extends throughout the visible and into the deep infra-red (chart 1).

**The "Cold Quartz" Lamp** The so-called cold quartz ultraviolet lamp is essentially a low vapor pressure low amperage (0.015 ampere), high potential (5,000 volts open circuit) glow discharge similar to the well known Geissler tube. The power consumed is small and consequently there is no great rise in temperature of the burner.

The spectral energy distribution of this type of ultraviolet lamp is illustrated in chart 7. Of the total radiation of all wavelengths less than and including the line at 3,130 angstroms, more than 95 per cent is contained in the resonance emission line of mercury

vapor at 2,537 angstroms. Two models of this type of lamp were examined—a small grid hand lamp in an aluminum reflector and a large hexagonal grid lamp in a large aluminum reflector, supported on a stand for body irradiation.

The erythemogenic efficiency of this type of lamp is high, but, as shown in chart 7, practically all the erythral effect is produced by the line at 2,537 angstroms. For this reason the question has arisen whether this type of ultraviolet radiation should be used for general body irradiation or whether its application should be confined to special conditions. The fact that the erythemogenic efficiency of a source is high is not necessarily a criterion of its suitability for therapeutic purposes.

**The Type G Mercury Glow Lamp** By providing suitable ionization by means of electrons emitted from a hot cathode, only a relatively low voltage is required

Chart 6—Relative spectral radiation

to excite resonance radiation in the glow discharge through mercury vapor. A typical example of this type of radiation is the new ultraviolet glow lamp in a bulb of special glass that absorbs almost completely all the ultraviolet rays of wavelengths shorter than about 2,800 angstroms. The operating temperature of this type of lamp is low, and the glow discharge practically fills the glass bulb.

The spectral energy distribution of this type of mercury vapor radiation is somewhat similar to that of the Mazda S-1 lamp in a corex glass bulb illustrated in chart 7. The total ultraviolet emitted being rather low, this type of lamp belongs to the category of "sun-lamps" marketed by a number of producers under a variety of trade names.

**The High Frequency Electrodes Discharge** The most recent production in ultraviolet therapeutic lamps is the electrodeless discharge, through mercury vapor, in a quartz bulb. The lamps examined were spherical

bulbs of quartz, or Corex-D, glass (without electrodes), which are placed within a helical conductor that carries the high frequency current, obtained from the transformer of a diathermy machine. The bulb is evacuated and contains a globule of mercury, the vapor of which is excited to luminescence by means of the high frequency discharge, from the 5,000 volt secondary of the transformer, passing through the helix surrounding the bulb. It is well known that the emission spectrum of the electrodeless discharge is essentially that of the neutral mercury atom, similar to that of the ordinary mercury arc, though close to the walls of the bulb there are some weak spark lines, not present in the hot quartz mercury arc lamp.

The spectral energy distribution, the total ultraviolet output, and the erythemogenic efficiency of this type of lamp were found to be closely the same as that of the ordinary mercury arc lamp (Uviarc) depicted in chart 7. Practically the only difference is the intrinsic

it would be more efficient to use a more intense source of these rays. For example, a powerful source of red and near infra-red rays is a 500 watt gas-filled tungsten filament lamp described on a preceding page. If the narrow band of red and near infra-red rays has a specific therapeutic action only when used separately from the rest of the spectrum of the tungsten lamp, it can be isolated by placing in front of the lamp a filter consisting of a sheet of red glass to shut out the shorter wavelengths, and a cell of water or a sheet of Corning heat-absorbing glass to intercept the infra-red rays of wavelengths longer than about 10,000 angstroms. The maximum of the filtered radiation will be in the spectral region of about 7,000 to 8,000 angstroms, with an intensity that far exceeds the ordinary neon glow lamp. From the clinical tests made by Cramer and Fechner<sup>9</sup> with a neon glow lamp, made for therapeutic purposes, it appears that the cold red ray lamp has little, if any, specific stimulating effect on the human body.

BIOLOGIC EFFECTS

This survey of the ever increasing number of types of lamps sold for therapeutic purposes, some of which are so weak in ultraviolet radiation that an exposure of from ten to thirty hours would be required to produce a minimum perceptible erythema, seems incomplete without some reference to their use.

During the past few years, experimental data have become available which show that the spectral band of ultraviolet radiation of wavelengths shorter than about 3,150 angstroms, occurring in sunlight and in some artificial sources of radiation, if sufficiently prolonged, has the power of preventing and of curing rickets. This is the underlying basis for exploiting ultraviolet of these wavelengths for general healing purposes. While this point of view may be too broad, the beneficial effects of short wavelength ultraviolet radiation in surgical tuberculosis and certain skin diseases are recognized.

An important and unanswered question is the minimum ultraviolet radiant flux (radiant power) that the source must emit in order to insure effective therapeutic action. Manifestly, the amount of ultraviolet radiation that can be applied to the body without producing a burn depends on the tolerance of the skin. This can be measured by the erythema produced. It is common knowledge that the erythema sensibility of the untanned skin is widely different for different persons and also widely different for the same person, depending on the amount of moisture on the skin. Hence, the erythemic response is in common use as an indicator of skin tolerance and of the amount of ultraviolet radiation that can be applied at any one time. Furthermore, in view of the wide variation in ultraviolet output of different kinds of lamps, and the wide variation in skin tolerance (twice as sensitive in summer as in winter), the safe procedure is to test the erythema reaction on a small area of each person before attempting to make exposures over large areas of the body.

Since most of these sources emit a wide band of ultraviolet radiation in the spectral region that produces an erythema (shown in the lower part of chart 7), the purpose of the erythema test is to avoid burns. The erythema test is not necessarily a measure of the thera-

Chart 7—Ultraviolet spectral energy distribution of various sources, also spectral erythemic response curve of the untanned skin and (the shaded areas) the rubescence energy which is the product of the spectral energy and the spectral erythemic response. E E erythemogenic efficiency the ratio of the shaded area to the total area. F factor F

brightness (flux density), which, in the ordinary quartz mercury arc, is concentrated in a luminous column less than 10 mm in diameter, whereas in the electrodeless discharge the radiation fills the entire bulb, some 6 to 8 cm in diameter.

9 The Cold Red Light—But few sources of radiation remain unexploited for therapeutic purposes. A recent European production is the so-called cold red light emitted by the neon glow discharge tube, familiar to all in the form of the sign-lighting tubes in show windows and street signs. The intensity of the total radiation emitted by the neon glow lamp is low. It consists of a narrow band of wavelengths in the orange-red part of the spectrum, with a maximum in the region of 6,500 angstroms, and a weaker maximum at about 8,500 angstroms. Neon emits practically no radiation of wavelengths longer than about 10,000 angstroms<sup>8</sup>. If the deep-penetrating rays in the red and near infra-red have a specific therapeutic action,

8 Coblentz W W Bull Bur Stds 9 81 116 1912 (No 191, 10 cents)

9 Cramer H and Fechner G Strahlentherapie 3B 474 1931

peutic action of the lamp, although, in the case of rickets, the spectral bands of erythema and therapeutic action appear to overlap. However, if a source should be obtained having a strong emission at from 2,700 to 2,900 angstroms with little or no radiation at 2,500 and 2,967 angstroms (lower part of chart 7), a far stronger dosage than with lamps now in use could be applied, without producing a burn.

In view of these considerations<sup>10</sup> the Council on Physical Therapy of the American Medical Association has adopted<sup>11</sup> and, until a more practical procedure is proposed, will use the erythema reaction as a basis for judging the effectiveness of ultraviolet lamps for two important reasons: (1) In the case of exposure to intense sources of ultraviolet radiation it is a simple and practical means of preventing severe burns, and (2) in the case of weak sources of ultraviolet radiation it is an efficient safeguard against possible fraudulent sale of lamps that are deficient in ultraviolet radiation.

The Council's specifications of minimum intensity are based on a comfortable and convenient operating distance (24 inches, or 61 cm) from the front edge

as well as the radiometric output, of the heterogeneous ultraviolet radiation from various sources is readily correlated with this emission line as a standard.<sup>12</sup>

From our experiments<sup>12</sup> it appears that a fifteen-minute exposure to a flux density of 20 microwatts per square centimeter (or a total of 180,000 ergs) of homogeneous radiation of wavelength 2,967 angstroms does not produce an erythema on the average untanned skin, though it may be somewhat too intense for a blond skin.

The Council has therefore adopted 20 microwatts per square centimeter of homogeneous radiation of wavelength 2,967 angstroms as the erythema unit (E U) of dosage, that is, 1 E U = 20 microwatts per square centimeter of radiation of wavelength 2,967 angstroms. For a further discussion of this subject the reader is referred to the original papers.<sup>12</sup>

With 20 microwatts per square centimeter for homogeneous radiation of wavelength 2,967 angstroms as a standard, in table 2 is given the erythemogenic equivalents of the heterogeneous (the total integrated) ultraviolet radiation of wavelengths shorter than and including 3,130 angstroms, required of various sources to produce a minimum perceptible erythema on the average untanned skin in fifteen minutes. For an exposure of sixty minutes the minimum permissible values are only one-fourth as large. That is to say, the total energy of unit intensity (20 microwatts per square centimeter) falling on a surface in fifteen minutes is the same as when one-fourth the intensity (5 microwatts per square centimeter) is used and the surface irradiated sixty minutes, or four times as long. From this table it may be noticed that the lower the erythemogenic efficiency of the source, relative to the standard line at 2,967 angstroms, the greater must be the total ultraviolet intensity of wavelengths shorter than and including 3,130 angstroms in order to meet the Council's requirements.

The specification of intensities given in table 2 are average values, observed in a 0-5 degree zone subtended by the center as the source, i. e., within a circle approximately 4 inches (10 cm) in diameter, lying in a plane at right angles to the axis of the reflector, at the specified operating distance (24 inches, 61 cm), from the front edge of the reflector, it constitutes the minimum values accepted by the Council on Physical Therapy.

#### CONCLUSIONS

It may be stated that in general the lamps submitted to the Council have an intensity that is several times the minimum requirements tabulated. The operating distance and the time of exposure to a given type of lamp are specified by the manufacturer.

In the newer lamps, such as the G-type glow lamp, the first productions did not comply with the specifications, but these lamps were promptly improved to meet competition with other types.

In general, the specifications by the Council have tended to improve the output of responsible lamp manufacturers, but at present there seems to be no means to prevent the exploitation of the public by the sale of cheap lamps emitting little or no ultraviolet radiation.

2737 Macomb, N W

TABLE 2—Erythemogenic Equivalents of Ultraviolet Radiation Required to Produce Erythema

Source	Ultraviolet Intensity in Microwatts per Square Centimeter
Sun midday midsummer midlatitude sea level	91
Carbon arc blue flame cored carbon in reflector no window	48
Carbon arc glass window opaque to 2 800 angstroms and shorter (estimated)	90
Mercury arc General Electric Mazda type S1 lamp high temperature arc in parallel with V shaped tungsten filament	63
Mercury arc General Electric Mazda type S2 lamp similar to the S1 lamp but smaller both in glass bulbs	93
Mercury arc types G1 and G5 low temperature, low voltage thermionic glow discharge glass bulb	109
Mercury arc high temperature high vapor pressure low voltage quartz tube	58
Mercury arc high frequency electrodeless discharge quartz bulb	60
Mercury arc low temperature low vapor pressure high voltage cold quartz Geissler tube discharge	36

of the reflector, at which distance the exposure can be made without burning the skin by coming in contact with the burner or by the infra-red rays. The ultraviolet intensity of the lamp shall be such that the time of exposure to produce a minimum perceptible erythema (one that disappears in less than twenty-four hours) will not be longer than fifteen minutes for a therapeutic lamp and sixty minutes for so-called sun-lamps.

As shown in chart 7, the emission line of the mercury arc lamp at 2,967 angstroms (297 mμ in the illustration) has an erythemogenic efficiency of 100 per cent relative to the rest of the spectral erythemic response. No other wavelength or group of wavelengths has such a high efficiency in generating an erythema. Hence the emission line of homogeneous radiation at 2,967 angstroms is a natural standard for evaluating sources of heterogeneous ultraviolet radiation.

The intensity and the erythemogenic action of the emission line of mercury at 2,967 angstroms is easily evaluated in absolute units, and the erythema action,

## Council on Pharmacy and Chemistry

## REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING  
REPORT  
PAUL NICHOLAS LERCH Secretary

## CARBARSONE

Carbarsone is a product of Eli Lilly and Company, originally proposed by Leake and his collaborators as a therapeutic agent in intestinal amebiasis. It was considered by the Council in 1931 and a preliminary report was published a short time later.<sup>1</sup> In view of subsequent publications on the use of this therapeutic agent and a report from the A M A Chemical Laboratory that the product is satisfactory chemically, the Council has now accepted Carbarsone-Lilly for inclusion in N N R. and has authorized publication of the following report.

Carbarsone is designated chemically as *p* carbamidophenylarsonic acid. It is closely related to tryparsamide, in common with both acetarsone and tryparsamide, it is a pentavalent arsenic compound.

An investigation carried out at San Quentin prison by Reed and his associates on the incidence of amebiasis in newly admitted prisoners and in the food-handling force of the institution, and the treatment of these cases with vioform or carbarsone, has been the subject of a series of progress reports. The final report<sup>2</sup> covers ninety-two treated cases, of which twenty-nine were removed elsewhere before any significant follow-up period could be established. Of the remaining sixty-three, thirty-one had been treated with vioform and thirty-two with carbarsone.

Stool examinations (smears stained with iron-hematoxylin) were made on three consecutive days at intervals of from two to four weeks on each patient. The vioform group was followed for an average period of 132 months (range, 7 to 18½ months), all but three of these patients remained negative (the latter were found to be positive at eight, ten and sixteen months, respectively). Of the carbarsone group, all thirty-two remained negative for an average period of 196 months (range, 13½ to 22 months). Of the original series of forty-two cases treated with carbarsone, one severe case did not remain negative after two courses. Of four others in which 5 Gm. of carbarsone was given in ten days, two showed recurrences six and seven weeks, respectively, after treatment. After a second course of carbarsone, these two remained negative for the one month of observation. All four patients were paroled before the follow-up period could be completed.

It appears from this unusually well controlled study, in which the possibility of reinfection was apparently relatively low, that carbarsone may be an unusually effective treatment in amebiasis.

Presson<sup>3</sup> presents results in forty cases of protozoiasis treated with carbarsone (eighteen *Endamoeba histolytica* alone, five *Endamoeba histolytica* associated with other protozoans, the remainder were *Endamoeba coli*, *Endamoeba nana*, *Trichomonas*, *Giardia*, *Chilomastix* singly or mixed). One course of 0.25 Gm. of carbarsone twice a day for ten days cleared all but two cases (one *Giardia* the other *Endamoeba histolytica*, *Chilomastix* and *Trichomonas* mixed) from six to fifty

follow-up examinations were made in each case but the periods of observation are not stated. The only side effects reported by Presson were flatulence and "hyperperistalsis" of the intestine but "no excessive diarrhea."

Anderson and Reed<sup>4</sup> state that about 10 per cent of patients with amebiasis are found to be refractory to carbarsone orally. These are cases usually of acute dysentery or diarrhea in which motile amebas are found. The authors present twelve cases in which carbarsone was administered rectally (200 cc. of a solution containing 1 per cent of carbarsone and 2 per cent of sodium bicarbonate) as an overnight retention enema, on alternate days for five such treatments. Usually a sedative was administered to permit retention of the enema, three patients could not retain the dose. Oral treatment was interrupted to avoid overdosage. The enemas relieved the acute symptoms but the amebas were not eradicated. Eight of these patients received carbarsone by mouth subsequently, four had one course, two two courses, and two three courses. In addition, adjuvants such as bismuth subcarbonate, vioform, acriflavine, heptylresorcinol and emetine were used variously in seven patients. The latter, and five patients receiving carbarsone alone, remained ameba free for an average period of five and one-fourth months, but two of the first group were found positive again at six and twelve months, respectively. These authors believe that patients should be followed for a period of two years after completion of therapy. Of course, in a period as long as this, as has been pointed out, it is impossible to distinguish recurrence from reinfection.

Anderson<sup>5</sup> reports eighty-eight cases of amebiasis in Panama treated with carbarsone. Eighty adults received a total of 5 Gm. in ten days, six children received about one-half the adult dose, two patients did not complete treatment. Thirty-seven of these cases were followed for a month (six or more specimens) and all but one were cleared and remained so for the period of observation. The data on the others are incomplete.

Chopra, Sen and Sen<sup>6</sup> investigated the effectiveness of carbarsone in thirty-one cases of amebiasis treated in Calcutta. Twenty-three had five or more (most had six) negative examinations on different days following cessation of treatment, four patients appeared to be cleared but the authors consider the number of post-treatment examinations insufficient. There were four failures. It is obvious that, as the authors admit, the criterion of cure used by them is not adequate for reasonable certainty of an ultimately satisfactory result. Nevertheless, the results obtained, as judged by this method, appear to be better than those obtained in India with the other agents commonly used. Chopra and his associates agree with the oft-repeated claim of the California workers that carbarsone is superior in therapeutic efficacy to acetarsone.

Anderson and Reed,<sup>7</sup> report one case of toxicity from carbarsone. This consisted of icterus, pain in the right upper quadrant, enlarged tender liver, numbness of the hands and legs, weakness and "generalized aches" in a patient who one year previously had had an enlarged tender liver following carbarsone therapy. The symptoms cleared in five days with no apparent residual effects. In addition, seven cases of gastric irritation occurred with a preparation purified by a different method, since abandoned.

Anderson and Reed<sup>7</sup> state that they have seen no evidence of skin, optic nerve or renal damage following the use of carbarsone clinically. The possibility of optic nerve destruction has been particularly emphasized, as carbarsone contains a modified amino group in para position to the arsenic atom similar to the arrangement in tryparsamide. Farrington (reported by Anderson and Reed<sup>7</sup>) administered graded doses up to totals of 150, 300, 600, 800 and 1200 mg. per kilogram over a period of forty-eight weeks (alternating four weeks of administration with four weeks of rest) without evidence of toxicity in thirty-three cases as determined by clinical examina-

3 Presson V G Treatment of protozoiasis with carbarsone to be published

tions (including visual field determinations) and tests on blood and urine, all at intervals of four weeks

In one case reported to the Council, 0.25 Gm was given twice a day for six days. On the fourth day severe headache developed, which persisted in milder form for the two subsequent days, on the fifth generalized itching occurred and on the sixth a light scaling erythematous rash was noted on the forearms. Administration was stopped and symptoms of toxicity cleared up largely within forty-eight hours.

Dr Frank Smythies, in a discussion before the Chicago Society of Internal Medicine, May 28, 1934, and in a subsequent written communication, reported several cases of severe toxic reactions from the administration of carbarsone in 0.25 Gm capsules.

"1 One patient with acute anebiasis took less than ten capsules of carbarsone and within a week had a dermatitis of the exfoliative type over the hands and arms.

"2 One patient took twenty capsules of carbarsone (three capsules daily) and experienced, after the fifth day, pulmonary edema of the larynx, chemical sore throat and very pronounced sneezing, lacrimation and running of the nose.

"3 One patient took carbarsone five days on and one week off (two capsules a day) and six weeks after treatment was begun came to me with a history of acutely swollen ankles, knees and wrists—a condition which the patient had never experienced before and which came on about the fourth week following the beginning of carbarsone therapy. When I saw him he had, in addition to moderate swelling about the soft parts of the joints named a liver four fingerbreadths below the rib margin (it was tender) and a spleen at least twice the normal size (it was readily palpable).

"4 One patient who took seven capsules of carbarsone over a period of three and one-half days, developed faulty vision and photophobia. There was moderate swelling of the eyelids, slight puffiness of the face and granular casts with a trace of albumin in the urine. Ophthalmoscopic examination showed moderate papillitis and moderate retinal edema.

"5 Several patients experienced aggravation of diarrhea, nausea and vomiting and vague pains in the stomach region, after from two to eight carbarsone capsules had been taken. One of these patients developed slight but definite icterus on the fourth day after beginning carbarsone therapy (two capsules a day)."

Dr Smythies<sup>8</sup> deprecates the present tendency toward the indiscriminate administration of fixed total doses of antiamebic drugs without regard to the sensitivity of the individual patient (or to the tissue damage that such remedies may produce) and often even without adequate diagnosis. He points out that adequate therapy often requires the use of a number of remedial agents and cautions against placing too much reliance on single 'specific' remedies.

Reed<sup>9</sup> emphasizes the necessity of determining by suitable tests the presence or absence of hepatitis (and impairment of renal function), guarding the use of arsenicals accordingly. He warns against overstandardization of treatment and points out the frequent necessity for adjuvant therapy such as alternating courses of viotorm with those of carbarsone with ten day rest periods intervening, tannin preparations and bismuth subcarbonate in cases presenting persistent dysentery or diarrhea, emetine in amebic hepatitis, dietary adjustment, colonic irrigations with antiseptics and other measures for secondary infection, proper surgical intervention when indicated in resistant cases.

Reed and Johnstone<sup>2</sup> summarize the results in 330 cases. Our conclusion is that carbarsone is a valuable addition to the treatment of amebiasis because of its effectiveness at least as high as any other single drug combined with low toxicity, capability of oral administration, noninterference with ordinary pursuits of the patient, lack of adjuvant requirements such as bed rest, diet, hospitalization and other drugs and finally its relatively low cost. We have found a certain number of patients resistant to carbarsone and all other therapy.

It appears that carbarsone is a valuable addition to the antiamebic armamentarium. It must be considered, however, that not a few patients are resistant to this agent as well as to other amebicidal drugs, and that while toxic reactions appear to be uncommon, a few serious accidents have occurred after administration of the usual therapeutic doses of carbarsone. The individual susceptibility to arsenic compounds of each patient must be evaluated and evidences of toxic manifestations must be watched for carefully, both during the period of therapy and, in view of the slow excretion of the administered arsenic,<sup>10</sup> for a reasonable time afterward.

## NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary

**CARBARSONE**—*p*-Carbamido-phenylarsonic acid—*p*-Carbamido-benzenearsonic acid— $\text{NH CONH C}_6\text{H}_4\text{As O (OH)}$   
—The *N*-carbamyl derivative of [*p*] arsanilic acid. Carbarsone contains from 28.1 to 28.8 per cent arsenic (As).

**Actions and Uses**—Carbarsone is proposed for the treatment of intestinal amebiasis. It is administered usually by mouth, in acute amebic dysentery or in resistant cases with motile amebas in the stools, retention enemas may be employed. While carbarsone is said to be less toxic than acetarsone and serious untoward effects appear to be uncommon, cutaneous disturbances and other reactions common to arsenic compounds have been observed. It has been suggested that owing to its chemical structure (in which a modified amido group is in para position to the arsenic atom, similar to the arrangement in tryparsamide) the administration of carbarsone may lead to injury of the optic nerve. While visual disturbances appear to be quite rare, the possibility of their occurrence should nevertheless be kept in mind during the therapeutic use of the drug. A moderate increase in intestinal activity may be observed. Carbarsone, in common with other arsenicals, should ordinarily not be employed in the presence of hepatitis or kidney damage. Excretion of the administered arsenic is relatively slow, suitable rest periods must therefore be interposed in the treatment to prevent cumulative effects.

The diagnosis of amebiasis depends on the observation of motile forms or cysts of *Endamoeba histolytica* in stool specimens (repeated examinations are often necessary) or their recovery by means of the proctoscope from the intestinal mucosa, positive diagnosis can often be made by the latter procedure when stool examinations are negative, and this is considered to be the more satisfactory as well as the more rapid method of diagnosis in many cases.

In view of the frequency of persistent infection in the absence of marked symptoms, adequate therapy includes reexaminations and repetitions of courses of treatment.

**Dosage**—Orally, for adults, the usual dose is 0.25 Gm twice a day for ten days. If necessary this may be repeated following a ten day rest period. For children the dosage may be reduced according to weight. As retention enemas, for adults, 2 Gm of the drug dissolved in 200 cc of warm 2 per cent sodium bicarbonate solution may be administered following a cleansing alkaline enema every other night for a maximum of five doses, if necessary. Because of the large dosage employed (a total of 10 Gm over a period of nine days) oral administration should be interrupted during this interval.

Manufactured by Eli Lilly & Company, Indianapolis. No U. S. patent. Carbarsone is a registered U. S. trademark but the firm disclaims proprietary rights to the name.

**Units** Carbarsone 2 Gm (31 grains)

**Packages** Carbarsone 0.25 Gm. (3 3/4 grains)

Carbarsone is a white, almost odorless powder having a slightly acid taste. It is very slightly soluble in water, slightly soluble in alcohol and nearly insoluble in ether and chloroform. Freely soluble in alkalis and alkaline carbonates. The water solution yields an acid reaction to litmus paper.

Transfer 1 Gm of carbarsone to a suitable test tube, dissolve in a solution containing 10 cc of sodium hydroxide solution and 10 cc of water, add 2 Gm of sodium hydrosulphite and warm the mixture to 50°C. A light yellow precipitate is formed in an excess of sodium hydroxide solution (distinction from acetarsone).

Dissolve 0.50 Gm of carbarsone in 2 cc of ammonia water, dilute to 5 cc with water and add 3 cc of magnesia mixture solution, no

<sup>8</sup> Smythies Frank. Editorial. Am J Digest Dis & Nutrition 1: 147 (April) 1934.

<sup>9</sup> Reed A. C. Amebiasis—A Clinical Summary. California & West Med 40: 6 (Jan) 1934.

<sup>10</sup> Chen M. Y., Anderson H. H. and Leake C. D. Rate of Urinary Arsenic Excretion After Giving Acetarsone (Stovarsol) and Carbarsone by Mouth. Proc Soc Exper Biol & Med 28: 145 (Nov) 1930.

precipitate forms (absence of inorganic arsenates), allow the solution to stand for some time or heat the solution for some time. A precipitate is produced. Add 10 cc of sodium carbonate solution to 1 Gm of carbarsone in a test tube and gently agitate the mixture. A complete solution results in five minutes. Shake 0.5 Gm of carbarsone for five minutes with 10 cc of diluted nitric acid filter the mixture and add a few drops of silver nitrate solution to the filtrate. At most only a very slight turbidity is produced within five minutes. Carbarsone melts with decomposition at 169 to 171 C. (the U. S. P. melting point determination method is to be used). Transfer 0.4 Gm of carbarsone to a test tube add 5 cc of 20 per cent sodium hydroxide stopper with a slotted cork from which is suspended a strip of moist red litmus paper and heat gently the litmus paper turns blue.

Dissolve 0.50 Gm of carbarsone in 2 cc of ammonia water and dilute to 10 cc with water. This solution conforms to the test for heavy metals when treated according to U. S. P. N. p. 439 beginning with warm it to about 50 C etc. [The test for absence of arsenic acid as described for trypanamide N. N. R. 1934 is not applicable to this compound].

Incinerate 0.5 Gm of carbarsone not more than 0.1 per cent residue remains. Heat about 0.2 Gm accurately weighed of carbarsone for six hours at 100 C the loss in weight does not exceed 11 per cent.

Determine the arsenic of carbarsone by the method for arsenic in arsenophenamine U. S. P. N. p. 67 the arsenic (As) content corresponds to from 28.1 to 28.8 per cent of the weight of the sample.

Transfer about 0.5 Gm of carbarsone accurately weighed to a 500 cc Kjeldahl flask. Determine the nitrogen content according to the method of Medical War Manual No. 6 Laboratory Methods of the U. S. Army Second Edition Revised page 222 beginning with Add 20 cc of concentrated H<sub>2</sub>SO<sub>4</sub>. The nitrogen content is not less than 10.7 per cent nor more than 11 per cent of the weight of the sample.

## Committee on Foods

### ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG Secretary

### JELKE'S GOOD LUCK VEGETABLE OLEOMARGARINE

**Manufacturer**—John F. Jelke Company, Chicago

**Description**—Margarine prepared from hydrogenated cottonseed oil, cottonseed oil, salt, and sucrose, churned in milk.

**Manufacturer**—The hydrogenated cottonseed oil is melted to a semiliquid state, churned with the cottonseed oil at a definite temperature, and then with pasteurized milk ripened with cultures of *Streptococcus lacticus* and associated aroma-producing strains. The resulting emulsion is solidified by cold water sprays, thoroughly cooled, and allowed to stand for a short period, subsequent to which salt and sugar are worked in and excess moisture is removed. The margarine is printed into 1, 2 and 5 pound blocks, which are automatically wrapped in parchment paper and packed in dated cartons.

**Analysis** (submitted by manufacturer) —

Protein (N × 6.25)	0.9
Sucrose (copper reduction method)	0.7

**Calories**—7.5 per gram 213 per ounce

### MEADS DEXTRI-MALTOSE WITH VITAMIN B (CONTAINS EXTRACTS OF WHEAT EMBRYO AND YEAST)

**Manufacturer**—Mead Johnson and Company, Evansville, Ind.

**Description**—Powdered mixture of Mead's Dextri-Maltose No. 2 (essentially maltose and dextrin) and extracts of wheat embryo and yeast to provide vitamins B and G.

**Manufacture**—The extract of wheat germ is prepared by macerating wheat germ in cold water the solution is filtered through a filter press. The extract of yeast is prepared by boiling a mixture of brewers' yeast and water the solution is separated by centrifugation. The extracts of wheat embryo and yeast are added to the dextri-maltose syrup prepared as described for Mead's Dextri-Maltose No. 2 (THE JOURNAL, Oct. 31, 1931, p. 1302) in such proportion that 2 Gm of the

finished Dextri-Maltose with Vitamin B will contain the extracts of 1 Gm of wheat germ and 0.3 Gm of yeast (Wheat embryo and yeast are both used as sources of vitamins B and G in that wheat germ is richer in B and yeast in G).

**Analysis** (submitted by manufacturer) —

**Calories**—3.9 per gram 111 per ounce

**Claims of Manufacturer**—A carbohydrate supplement to milk for use in infant feeding, supplying liberal amounts of vitamins B and G, copper and iron.

### UNSWEETENED COOKING CHOCOLATE

- (1) CENTRELLA BRAND
- (2) COLONIAL
- (3) EDWARDS BRAND
- (4) MY-TE-GOOD BRAND
- (5) N J C PURE FOOD
- (6) QUINCY BRAND
- (7) SUPREME COURT BRAND

**Distributors**—(1) Central Wholesale Grocers, Inc., Chicago, (2) Merchants Service Corp., San Francisco, Chicago and New York, (3) The William Edwards Company, Cleveland, (4) Donahoe's, Pittsburgh, (5) Northern Jobbing Company, St. Paul, (6) Quincy Wholesale Grocer, Inc., Quincy, Mass., (7) The W. H. Dunne Company, Norwich, New York.

**Manufacturer**—Moffat, Inc., Boston

**Description**—Ground cacao nibs or "chocolate liquor" in cake form. Same as Moffat Cooking Chocolate Unsweetened, THE JOURNAL, Jan. 20, 1934, page 213.

**Claims of Manufacturer**—Conforms to the United States Department of Agriculture definition and standard.

- (1) ELCO BRAND CRYSTAL WHITE TABLE SYRUP
- (2) ELCO BRAND GOLDEN TABLE SYRUP
- (3) HAPPY HOME BRAND CRYSTAL WHITE SYRUP
- (4) RED W BRAND GOLDEN SYRUP

**Distributors**—(1) and (2) I. Cohen Grocer Co., St. Louis (3) and (4) Wulfin Grocer Co., St. Louis

**Packer**—Union Starch and Refining Company, Granite City, Ill.

**Description**—(1) and (3) A table syrup, corn syrup sweetened with sucrose flavored with vanilla. The same as Union Brand Crystal White Syrup (THE JOURNAL, Sept. 3, 1932, p. 833).

(2) A table syrup, corn syrup flavored with refiners' syrup. The same as Union Brand Golden Table Syrup (THE JOURNAL, July 23, 1932, page 309).

(4) A table syrup, corn syrup flavored with refiners' syrup. The same as Golden Drip Brand Golden Table Syrup (THE JOURNAL, May 26, 1934, page 1763).

### LAND O'LAKES UNSWEETENED EVAPORATED MILK

**Distributor**—Land O'Lakes Creameries, Inc., Minneapolis

**Description**—Unsweetened evaporated milk.

**Manufacture**—The procedure of evaporation and canning, and the analysis are essentially the same as for the usual evaporated milk (THE JOURNAL, April 16, 1932, p. 1367).

**Claims of Manufacturer**—See announcement on the advertising of the Evaporated Milk Association (THE JOURNAL, Dec. 19, 1931, p. 1890).

**CALIFORNIA HOME BRAND TOMATO CATSUP**

**Manufacturer**—California Conserving Company, Inc., San Francisco

**Description**—Tomato catsup containing tomatoes, sucrose, distilled vinegar, sodium chloride, onions, cassia, mace, cloves, garlic, celery seed, pepper

**Manufacture**—Sorted ripe tomatoes are washed in revolving spray washers, inspected, passed through live steam to loosen the skin, pulped, screened to remove seeds, cores and peelings, and conveyed to cooking kettles. Formula proportions of the ingredients (excepting distilled vinegar) are cooked for fifteen minutes, distilled vinegar is added and the steam is turned off until batches are tested for refractometer reading, mold count and color reading and when found to conform to the standard for this brand of catsup are screened, and automatically bottled at 88 C

**Analysis (submitted by manufacturer) —**

	per cent
Moisture and volatile substances	67.0
Total solids	33.0
Ash	5.5
Fat (ether extract)	0.4
Protein (N $\times$ 6.25)	2.5
Reducing sugars as invert sugar	8.0
Sucrose	16.1
Crude fiber	0.3
Titrate acidity as citric acid	2.0
Volatile acid as acetic	0.9

**Calories**—1.2 per gram 34 per ounce

**Claims of Manufacturer**—The speed of handling tomatoes from field to finished product keeps mold and bacteria at a minimum and protects tomato flavor and color

**MORO PURE VIRGIN OLIVE OIL**

**Distributor**—E. Cerruti, Inc., New York City

**Special Distributor**—Mencacci & Co., Inc., Jamaica N. Y.

**Manufacturer**—Tommaso Moro & Figli, Genoa, Italy

**Description**—Imported Italian first cold pressing olive oil

**Manufacture**—Selected sound olives from different districts in Italy are pressed cold to expel the oil

The first pressing oil only is filtered, refined and sealed in tins under this brand name

**Analysis (submitted by manufacturer) —**

Specific gravity 15 C/15 C	0.918
Refractive index at 25 C (Zeiss)	61.6

Iodine number (Hubb)	81
Free fatty acids as oleic acid	0.6
Cottonseed oil	None
Mineral oil	None
Peanut oil	None
Sesame oil	None

**Calories**—9 per gram 256 per ounce

**Claims of Manufacturer**—Pure virgin olive oil

**ARROWHEAD SOFT SPRING WATER**

**Distributor**—California Consolidated Water Co., Los Angeles

**Description**—Spring water of low mineral content and practically free of micro-organisms

**Collecting and Bottling**—The springs are enclosed in a sealed tunnel located at an elevation of 5,000 feet in an uninhabited area of the San Bernardino Mountains, California. The water (10 C) flows by gravity through steel pipe-lines to cement holding tanks, from which it is loaded by gravity flow into special railway tank cars. The water is delivered into holding tanks in the cities, where it is automatically bottled and distributed.

All incoming demijohns are thoroughly cleansed with 2.5 per cent sodium hydroxide solution, sprayed with chlorine water and flushed with well and distilled water, forty-nine immersions and rinsings occur during this process.

The tunnel and pipe-line are cleaned regularly with a solution of sodium hypochlorite (NaOCl) and copper sulphate (CuSO<sub>4</sub>) and properly flushed with water thereafter. A filter placed in the line removes any flotation material. Cement storage and holding tanks are cleaned after each unloading by spraying with a solution of sodium hypochlorite (two ounces per 50-75 gallons) and flushing with fresh water. They are scrubbed

at frequent intervals. The interior of the tank cars is coated with wax, which is replaced each year. The tanks are cleaned as described for the cement tanks after each unloading and prior to reloading.

**Analysis (submitted by manufacturer) —****Sanitary Analysis**

Silica (SiO <sub>2</sub> )	15.3

**Micro-Organisms**—Bacterial examination shows none or very few bacteria per cubic centimeter and no *Bacillus coli*.

**Claims of Manufacturer**—A pure spring water of low mineral content

- 1 BAKEBEST BAKERS FLOUR
- 2 BAKER'S SPECIAL HARD WHEAT FLOUR
- 3 CRAFTSMAN BAKERS FLOUR
- 4 LA CAMPANA FLOUR
- 5 MELLO LOAF BAKERS FLOUR
- 6 VICTOR FLOUR

**Manufacturer**—Liberty Mills, San Antonio, Texas

**Description**—(1) Hard red winter wheat patent flour, bleached (2) and (3) Hard red winter wheat standard patent flour, bleached (4), (5) and (6) Hard red winter wheat first clear flour, bleached

**Manufacture**—Selected hard red winter wheat is cleaned, scoured, tempered and milled by essentially the same procedures as described in THE JOURNAL, June 18, 1932, p 2210. Chosen flour streams are blended and bleached with nitrogen trichloride (one-ninth ounce per barrel)

- (a) WORCESTER SALT (A-BULK)
- WORCESTER SALT (CANNERS "A")
- WORCESTER SALT (FLOUR)
- WORCESTER SALT (FLOUR "AA")
- (b) WORCESTER SALT (FLAKE)
- WORCESTER SALT (FLAKE CHEESE)
- WORCESTER SALT (FLAKE FLOUR)
- WORCESTER SALT (BAKERS FLAKE)

**Manufacturer**—Worcester Salt Company, New York

**Description**—Salts for commercial purposes in "flake" and cube forms. The flour salts contain 1 per cent added calcium phosphate, which tends to preserve their free running properties.

**Manufacture**—The preparation is the same as that described for Worcester Salt (THE JOURNAL, April 22, 1933, p 1237). One per cent calcium phosphate is added to the flour salts before packing.

## SERUM THERAPY IN POLIOMYELITIS

The prevalence of epidemic poliomyelitis in southern California has revived interest in treatment of the acute disease with serum. Largely as a result of the studies of Aycock and his associates,<sup>1</sup> opinion had become crystallized that convalescent serum was highly effective in preventing and minimizing paralysis if given in the preparalytic stage. In the New York epidemic of 1931, Park carried out a rigorously controlled therapeutic experiment in which unselected alternate patients received convalescent serum in the preparalytic stage. He could find no difference either in incidence of paralysis or in mortality rates in the two groups.

The treatment of the acute stage of poliomyelitis has now been reviewed by Harmon,<sup>2</sup> who has pointed out that many preparalytic cases are destined never to result in paralysis. In other words, many instances of early poliomyelitis diagnosed in the preparalytic stage by pleocytosis and an increase in protein in the cerebrospinal fluid are cases of nonparalytic poliomyelitis. According to data collected from the literature of 531 untreated preparalytic cases of poliomyelitis, paralysis never appeared in 380 (71.5 per cent). The implications of these data on the alleged beneficial results of convalescent and other serums are obvious.

Apparently there are no clear-cut experimental data that serum of any type affects the course of the experimental disease in monkeys. The *in vitro* virucidal test that utilizes monkeys is the only reliable test of poliocidal properties in a serum. It has long been assumed but yet has to be definitely proved that the therapeutic efficacy of convalescent or other serum is measured by this test. Indeed, the administration of tested serum during the incubation period of the experimental dis-

ease, even in the preparalytic stage, has been a signal failure except in the hands of a few investigators. In these reports the conclusions drawn might well be questioned on the basis of the data presented.

During the last five years, many new facts concerning the incidence and distribution of the poliocidal substances have been developed. These substances are to be found in comparable quantity in the serum of most adults as well as in the serum of poliomyelitis convalescents. Such results have led to the hypothesis that subclinical attacks of poliomyelitis are as common as subclinical diphtheria and scarlet fever. Storage of human convalescent serum (and presumably normal human serum) for two or three years has been shown to have little effect on the concentration of neutralizing substance. The poliocidal substance is relatively thermostable, withstanding 56 C for half an hour, and is little affected by filtration through Berkefeld or Seitz filters.

The severity of the epidemic, the place on the epidemic curve when treatment is applied, the age of the patient and the type and degree of orthopedic after-care are all factors of as much importance in estimating the outcome from poliomyelitis as the use of serum itself. Notwithstanding the total failure of statistical presentations to make a case for serum therapy in this disease, clinical observations almost universally indicate rapid symptomatic response to serum administration. There seems to be an immediate drop in temperature and improvement in symptoms that cannot be totally disregarded. These clinical results have been shown equally after both normal adult serum and convalescent serum, so that there seems to be little preference between these two types of serum.

Reports on the use of serum for passive protection in epidemics are inconclusive. In two villages in Sweden, Davide<sup>3</sup> protected seventy-three persons under the age of 25 years with convalescent serum, while a group of eighty-four persons of similar age served as an uninoculated control group. Among the first group but one case of poliomyelitis occurred, while in the latter group there were fourteen cases of the frank disease and several alleged "abortive" cases. Brebner<sup>4</sup> protected 1,300 children with whole adult blood in a single town during the eastern Pennsylvania epidemic of 1932 without a single frank instance of poliomyelitis occurring in the protected group, while thirty-two additional cases of paralysis occurred in the remaining child populace of approximately 3,000 children. Henry and Johnson<sup>5</sup> reported on the immunization of 2,255 children, largely with parents' whole blood, during the Philadelphia epidemic of 1932. Four cases of frank

poliomyelitis and eight nonparalytic cases developed in this group, an attack rate greater than that in the general populace. It is certain in the data of the latter authors, as well as in the data of Davide, that many of these failures should not be charged against the serum, as the interval between injection of serum and onset was less than the incubation period of the disease. It will be difficult to evaluate the efficacy of a prophylactic agent in poliomyelitis on account of the low attack rate even in epidemics, and because there is no method of defining the susceptible group. More data and observation are needed before the final opinion can be given as to the value of serum treatment and prophylaxis in poliomyelitis.

### MEDICAL ETHICS AND NEW METHODS OF PRACTICE

Gradual changes in the nature of our civilization have brought ever more complex problems for solution by the medical profession. As has been stated repeatedly in these columns, the ethical principles which guide medicine are fundamentally so sound that they may be adapted to any situation arising in medical practice, provided those concerned wish to observe the spirit of these principles. Nevertheless, physicians involved in new types of organization, such as contract practice, industrial practice, hospital practice, university practice, and the practice of medicine by lay corporations which employ physicians, have been brought before the judicial councils and committees on ethical relations of various medical bodies, because of infringements of these ethical principles. In some cases there have apparently been difficulties of interpretation. To overcome these difficulties, the Judicial Council of the American Medical Association, at the Cleveland session, presented three amendments to the Principles of Medical Ethics. These were heartily endorsed by the Reference Committee on Amendments to the Constitution and By-Laws and then adopted by the House of Delegates as guiding principles for organized medicine.

The term "contract practice" is anathema to the vast majority of individual practitioners in this country, yet contracts of all kinds are matters of daily life in all forms of industry. Conceivably there are situations in which the practice of medicine under a contract may be necessary or desirable. In order to elucidate this phase of medical practice, the Principles of Medical Ethics, chapter II, article V, section 2, is now amended by addition of the following wording:

By the term "contract practice" as applied to medicine is meant the carrying out of an agreement between a physician or a group of physicians as principals or agents and a corporation, organization or individual to furnish partial or full medical services to a group or class of individuals for a definite sum or a fixed rate per capita.

Contract practice per se is not unethical. However, certain features or conditions if present make a contract unethical, among which are: 1 When there is solicitation of patients directly or indirectly. 2 When there is underbidding to secure the contract. 3 When the compensation is inadequate

to assure good medical service. 4 When there is interference with reasonable competition in a community. 5 When free choice of a physician is prevented. 6 When the conditions of employment make it impossible to render adequate service to the patients. 7 When the contract because of any of its provisions or practical results is contrary to sound public policy.

Each contract should be considered on its own merits and in the light of surrounding conditions. Judgment should not be obscured by immediate temporary or local results. The decision as to its ethical or unethical nature must be based on the ultimate effect for good or ill on the people as a whole.

Group practice and clinical practice are also phases of medical work that have aroused opposition in many communities, because of the introduction of advertising methods and commercial promotion into their work. In some places groups or clinics have employed business managers, unfamiliar with the medical point of view, who have attempted to introduce unprofessional methods into medical practice. In order to establish the proper relationship between groups and clinics with the individual practice of medicine, the Principles of Medical Ethics will now contain the following statement:

The ethical principles actuating and governing a group or clinic are exactly the same as those applicable to the individual. As a group or clinic is composed of individual doctors, each of whom, whether employer, employee or partner, is subject to the principles of ethics herein elaborated, the uniting into a business or professional organization does not relieve them either individually or as a group from the obligation they assume when entering the profession.

Regardless, however, of the damage wrought to scientific medicine by physicians who engage in contract practice or by groups of physicians competing with the individual practitioner, the worst possible type of new methods in medical practice is the incorporation by business men of organizations to engage in the practice of medicine, employing physicians on salaries and exploiting the services of these physicians unethically to the public. The most conspicuous example of such an organization is the United Medical Service, Inc., which began a few years ago to advertise its services to the people of Chicago. Regarding such types of medical practice, the Judicial Council was definite. The Principles of Medical Ethics now contains the following statement:

It is unprofessional for a physician to dispose of his professional attainments or services to any lay body organization, group or individual, by whatever name called or however organized under terms or conditions which permit a direct profit from the fees, salary or compensation received to accrue to the lay body or individual employing him. Such a procedure is beneath the dignity of professional practice, is unfair competition with the profession at large, is harmful alike to the profession of medicine and the welfare of the people, and is against sound public policy.

As was stated in the introduction to these comments, these modifications of the Principles of Medical Ethics do not in any way modify the basic character of these principles. The Principles of Medical Ethics was established for the protection of the public primarily. Methods of promotion that sell medical practice on the basis of exaggerated claims, on a fee basis rather than

the quality of service rendered, methods of practice that break down the intimate personal relationship that must exist between doctor and patient, methods that delegate the responsibility of the attending doctor to a group or a corporation or a business manager, carry with them a menace to the life and health of the people who are served

Physicians will do well to familiarize themselves with these new statements of principle, now a part of the ethics of organized medicine. The young physician who is tempted by the offer of some commercial agency to enter into such schemes or combinations should bear in mind that he thereby jeopardizes his entire future in the practice of medicine and sacrifices the medical birthright for which he has already paid six or seven years of his life

#### A POLIOMYELITIS VACCINE

The attention devoted in newspapers and current periodicals to experiments now under way in New York for the development of a vaccine against poliomyelitis recalls the fact that such attempts are not wholly new. As early as 1910, Flexner, Lewis and others attempted to develop an immunizing agent of this type. Abramson in 1917, working in the Laboratories of the Department of Health of the City of New York, tested the value of a vaccine prepared from a virus killed by heat according to a method used by Semple for developing a vaccine against rabies. In his experiments, five monkeys each received successive vaccinations with 5 cc of a 10 per cent emulsion, each dose of which had been heated to 55 C for half an hour. Since that time many other investigators have attempted to produce a vaccine that might be established as efficacious, but thus far the results have not proved satisfactory. Now Dr. Maurice Brodie, working in the Laboratories of the Department of Health of the City of New York, with funds provided by the Rockefeller and other foundations, has developed a vaccine that seems to possess the likelihood of efficacy in the diagnosis and treatment of this disease. Influenced by the earlier work already mentioned and also by the favorable results recently obtained with antigens inactivated by germicides in the prevention of other virus diseases, investigators have attempted to develop a new antigen against poliomyelitis. It was felt that previous workers had not used sufficiently large doses of the antigen and that their tests for immunity were too severe, since convalescent monkeys are only relatively immune.

According to a special communication from Dr. William H. Park, the first experiments with virus inactivated by formaldehyde produced an appreciable immunity in a majority of the animals inoculated. It was found, however, that a concentration of 0.3 per cent of solution of formaldehyde was too irritating to the skin, then with the use of the incubator instead of the icebox temperature a lower concentration of the germicide was used. With antigens prepared in this

way the majority of monkeys inoculated proved resistant to direct intracerebral inoculation of the virus. Moreover, serum obtained from these monkeys possessed neutralizing substances against the virus of poliomyelitis. These antigens rarely produced any irritation of the skin when injected intracutaneously. Using extraordinary precautions, the group in charge of these investigations decided to test out the antigenic properties on themselves before attempting inoculation of children with the antigen. Several members of the research group were injected with a vaccine prepared by adding formaldehyde to a suspension of material from the infected spinal cord. It is proposed, after testing the blood of those who have been inoculated to determine the extent of the immunity developed, to carry the investigations further, inoculating children against this disease. The vaccine will, of course, have been established as absolutely harmless by the injection into the members of the committee and also as to its efficacy by the studies that have been made on monkeys inoculated with virus following inoculation with the vaccine.

Here is a well controlled scientific experiment in which the safety of all those concerned is guaranteed by modern scientific methods. If successful, it should yield valuable information for the future. It should do much to develop a means for preventing one of the most dreaded of diseases, which strikes fear to the hearts of parents in every community in which it appears.

#### Current Comment

##### SCURVY AND CLOTTING OF BLOOD

Although clinical scurvy has become more or less of a rarity in civilized countries, interest in the disease as produced in experimental animals continues. It was in this connection that the first vitamin was synthesized in the laboratory. Again, the success in elucidating the etiology of scurvy and in establishing effective treatment has led to the hope of obtaining further information on the details of the pathogenesis of the disease through experimental studies. Widespread hemorrhage has long been noted as one of the features of the pathology of scurvy, so that attention has been given to changes in the blood itself. Thus concentration of the blood, decrease both in red cells and in hemoglobin, diminution of resistance to hemolysis and decrease in serum proteins have been reported by various investigators. In a recent study Presnall<sup>1</sup> has paid special attention to the alterations of the clotting of the blood in scurvy. It was observed that increase in clotting time is the earliest sign of the disease in guinea-pigs, a measurable change taking place before the appearance of the usual symptoms. At the same time a marked decrease in the number of platelets was demonstrated and, in corroboration of other investigations, a definite anemia. It was further observed that, when the blood

<sup>1</sup> Presnall, A. K. *J. Nutrition* 8: 69 (July) 1934

of scorbutic guinea-pigs was allowed to clot and then either centrifugated or permitted to synerese, from two to three times more serum is obtained than when normal blood is similarly treated. These observations indicate that, in addition to structural defects in the vascular system, the blood itself undergoes alterations, possibly physical as well as chemical, that may influence the occurrence of hemorrhage in scurvy

## Association News

### MEDICAL BROADCASTS Columbia Broadcasting System

The American Medical Association broadcasts on a Western network of the Columbia Broadcasting System each Thursday afternoon on the Educational Forum from 4 30 to 4 45, Central daylight saving time. The speaker will be Dr W W Bauer. The next three broadcasts will be as follows

August 2 Dog Days  
August 9 Death Angel  
August 16 Black Widow

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS, EDUCATION, PUBLIC HEALTH ETC)

### ALABAMA

**Dr McLester Honored**—The Jefferson County Medical Association gave a dinner at the Tutwiler Hotel in Birmingham, July 7, in honor of Dr James Somerville McLester, President-Elect of the American Medical Association. Speakers reviewing the professional and civic activities of Dr McLester included Dr George S Graham, president of the county society, Dr Cabot Lull, Birmingham, Dr William M Cunningham, Jasper, president of the state medical association, Dr James E Paullin, Atlanta, George H Denny, DCL, president of the University of Alabama, and C B Glenn, superintendent of schools of Birmingham

### CALIFORNIA

**Jailed for Narcotic Violation**—Dr Leman D Cruce, San Diego, is now serving a fifteen months sentence in the federal prison on McNeil Island, Wash, for violation of the narcotic laws. He went to trial in the U S District Court at San Diego on five counts. Two of the charges were dismissed, but he was found guilty of the remaining three, March 9. On each of these he was sentenced to serve fifteen months, the sentences to run concurrently

**Changes at University**—Included among recent promotions at the University of California Medical School, San Francisco, are the following

Dr Edward L Munson professor of preventive medicine  
Dr Edward B Shaw associate clinical professor of pediatrics  
Nathan Shock Ph D assistant professor of physiology  
Dr Hamilton H Anderson assistant clinical professor of pharmacology  
Dr Keene O Haldeman assistant clinical professor of orthopedic surgery

**Ground Squirrel Eradication**—A year's campaign to eradicate ground squirrels will be carried on in Tulare County under a special fund of \$25 000 appropriated by county supervisors, according to the bulletin of the state board of health, July 7. The state board recently conducted a survey of bubonic plague in several counties, including Tulare as the result of a noticeable increase in the ground squirrel population. Six ground squirrels from Tulare County were found to be plague infected, June 9, according to *Public Health Reports*. June 16, four ground squirrels and one wood rat from Modoc County were found to be plague infected

**Infantile Paralysis in San Francisco**—Dr Jacob C Geiger health officer of San Francisco issued a statement July 19 on the present status of the epidemic of poliomyelitis

in San Francisco. Ninety-seven cases have occurred since May 1, with eight deaths. No new case had been reported for one week and only eleven cases were in quarantine, most of them in hospitals. The department of health has been assisted by an advisory committee comprising Karl F Meyer, Ph D, director, Hooper Foundation, University of California, Dr William Palmer Lucas, representing the San Francisco County Medical Society, Dr Edward B Shaw, University of California School of Medicine, Dr Le Roy C Abbott, orthopedic surgeon, Dr Harold K. Faber, Stanford University School of Medicine, Dr James W Ward, member, health advisory board, Dr Adolph E Schmidt, member, health committee board of supervisors, Dr Isaac W Thorne, president, San Francisco County Medical Society, and A J Gallagher, chairman, finance committee, board of supervisors

### COLORADO

**Society News**—At the midsummer meeting of the Arkansas Valley Medical Association in Canon City, July 14, speakers included Drs John W Ames, Denver, on "Difficult Infant Feeding Cases", George P Lingenfelter, Denver "Treatment of Eczemas, Infantile and Adult", William P McCrossin Jr, Colorado Springs, "Sterility, Its Diagnosis and Treatment," and Fred M Heller, Pueblo, "Treatment of Nephritis." Features of the entertainment were a trap shoot and golf tournament—Speakers before the Boulder County Medical Society in Boulder, June 14, were Severance Burrage, Ph D, and Bertram B Jaffa, Denver, on "Microbial Fingerprints, Their Relation to Respiratory Infections," and "Immunization Campaign in Denver," respectively—Dr William S Bartholomew, Manzanola, among others, spoke before the Crowley County Medical Society in Ordway, June 13, on venereal diseases—At a meeting of the Fremont County Medical Society in Canon City in May, Dr Alexander D Waroshill, Florence, presented a paper on "Oxygen Therapy"—Dr George L Pattee, Denver, among others, discussed "Treatment of Maxillary Sinusitis" before a joint meeting of the Larimer County Medical Society and the woman's auxiliary, June 6, in Fort Collins

### CONNECTICUT

**Campaign Against Mosquitoes**—Hundreds of men are employed under federal auspices in eliminating the breeding places of mosquitoes in Connecticut. R C Botsford of the state experimental station in New Haven stated that in a few months workmen will have drained all but 500 of the 18 000 acres of salt marsh along the Connecticut shores. About \$100 000 is being expended on the project. An attempt is being made in this campaign to keep water from flooding marshes at high tide with the use of tide gates. These gates, which have been installed at Lighthouse Point and Indian Neck, hold the tide back from the marshes, lowering the water level of the upper creek and thus allowing the ditches to function normally. In this campaign, local chambers of commerce, boards of health and town officials have pledged themselves to keep ponds, ditches, dumps and rain barrels clear of breeding facilities

### DELAWARE

**Society News**—Dr Isidor S Ravdin, Philadelphia, addressed the New Castle County Medical Society in Wilmington, May 15, on "Use and Abuse of Fluids." Dr John A Kolmer, Philadelphia, addressed the society, April 17, on "Present Status of Biologic Therapy"

**Dr Orr Honored**—Dr William P Orr Jr, Lewes, was honored at a dinner given by the Sussex County Medical Society, June 21, in commemoration of his completion of fifty years of practice. Dr Robert B Hopkins, Milton, presented Dr Orr with a loving cup. Dr Orr is president of the Delaware State Board of Health and previous to his retirement a few years ago was medical officer in charge at the Delaware Breakwater Quarantine Station of the U S Public Health Service

### FLORIDA

**State Board Election**—Dr Simon E Driskell Jacksonville was elected president of the Florida State Board of Medical Examiners June 12, and Dr Horace A Day, Orlando, was chosen vice president. Dr William M Rowlett, Tampa, was reelected secretary

**Munch Denied a License**—It is reported that the state board of medical examiners refused to renew the license to practice medicine in Florida of Dr George A Munch, Tampa, at its meeting in Jacksonville, June 12. Munch was convicted

in the federal courts in 1926 and served a term in the Atlanta penitentiary on charges of using the mails to defraud in connection with the Florida diploma mill

**Society News**—Dr Frederick K Herpel, West Palm Beach, was elected president of the Florida Radiological Association at its annual meeting in Jacksonville, April 30, Dr Wilfred McL Shaw, Jacksonville, secretary for many years, vice president, and Frazier J Payton, Miami Beach, secretary—Dr Thomas H Wallis, Ocala, was recently elected president of the Central Florida Medical Association, and Dr James L Strange, McIntosh, secretary

### GEORGIA

**Society News**—Dr Launcelot Minor Blackford was installed as president of the Atlanta Clinical Society, recently, succeeding Dr Joseph C Massee—At a meeting of the Georgia Medical Society, May 22, Dr John L Elliott, Savannah, discussed pneumothorax, and Dr St Julien R de Caradeuc, Savannah, reported two unusual cases of the eye—Speakers before the Crisp County Medical Society at Cordele, May 17, were Drs Calvin B Stewart, Atlanta on cancer and Richard Hugh Wood, Atlanta, glandular fever—Dr Floy S Rogers, Coleman, read a paper on "Cardiac Conditions Associated with Pain" before the Randolph County Medical Society at Cuthbert, June 7—Dr Samuel A Boland, Jefferson, addressed the Jackson-Barrow Counties Medical Society, June 4, on "Rheumatism in Children"—Dr James L Campbell read a paper on "Cancer as We Find It in Georgia. Its Diagnosis and Treatment" before the Fulton County Medical Society in Atlanta, July 5

### ILLINOIS

**Personal**—Dr Roy Sexton, Streator, received the merit award of Northwestern University Alumni Association on "illumination night" in Evanston, Ill, preceding the annual commencement exercises, June 15 The award is a certificate and is given annually to alumni for "worthy achievement which has reflected credit upon their alma mater"

### Chicago

**Dr Davis Made Emeritus Professor**—Dr Haim I Davis, professor of psychiatry at the University of Illinois College of Medicine since 1926 has been made emeritus professor, effective September 1 Dr Davis has been requested to continue with his teaching, however He has been associated with the school since 1908

**United Medical Service**—Superior Judge James J Kelly refused to vacate an order granting the state of Illinois leave to file quo warranto proceedings against United Medical Service, Inc, July 14 These proceedings, instituted May 12, question the right of the clinic to engage in the corporate practice of medicine under the provisions of the medical practice act of Illinois The court granted the request of the attorney for the clinic to have a jury trial and gave him sixty days in which to file a bill of exceptions and thirty days in which to demur to the petition for quo warranto the *Chicago Tribune* reports (THE JOURNAL, May 19, p 1686)

**Dr Wallgren Gives Sachs Lectures**—Dr Arvid Wallgren, professor of pediatrics and chief of the Children's Hospital at Gothenburg, Sweden, delivered the Theodore B Sachs resident lectures in tuberculosis of the University of Illinois College of Medicine, June 6-7 These lectures were established at the college for a five year period by the Chicago Tuberculosis Institute During the reunion of the alumni of the college, Dr Edward W A Ochsner professor and head of the department of surgery, Tulane University School of Medicine New Orleans, gave the alumni memorial lecture on "Postoperative Care in Abdominal Surgery Based on Clinical and Experimental Observations"

### INDIANA

**Society News**—Speakers before the Fifth District and Parke-Vermillion County medical societies at Turkey Run, June 23, were Drs William W Bauer, Chicago, and George E Brown, Rochester, Minn on 'The Medical Profession and the Public Health' and 'Newer Ideas of Hypertension, respectively

**Health at Evansville**—Telegraphic reports to the U S Department of Commerce from eighty-six cities with a total population of 37 million for the week ended July 14 indicate that the highest mortality rate (21.8) appears for Evansville and that the rate for the group of cities as a whole was 10 The mortality rate for Evansville for the corresponding week

of 1933 was 11.1 and for the group of cities, 9.6 The annual rate for eighty-six cities for the twenty-eight weeks of 1934 was 12 as against a rate of 11.4 for the corresponding period of 1933 Caution should be used in the interpretation of these weekly figures, as they fluctuate widely The fact that some cities are hospital centers for wide areas outside the city limits or that they have large Negro populations may tend to increase the death rate

### IOWA

**Society News**—A symposium on gastric and duodenal ulcer constituted the meeting of the Black Hawk County Medical Society at Wameso Lodge, June 19, speakers were Drs Walter L Palmer and Lester R Dragstedt, both of Chicago—Dr Donald P Abbott, Chicago, addressed the Cerro Gordo County Medical Society, June 21, on "Indigestion, the Diagnosis of Stomach Disorders and Their Treatment"—At a meeting of the Clinton County Medical Society, June 7, Drs Howard R Hartman and Joseph G Mayo, Rochester, Minn, spoke on "Lesions of the Small Intestine Other Than Peptic Ulcer" and "Secondary Anemias," respectively—The Hardin County Medical Society was addressed in Iowa Falls, June 26, by Dr Julia Cole, Iowa Falls, on "Diagnosis and Treatment of Bronchial Asthma"

### KANSAS

**Executive Secretary for State Society**—Mr Clarence Munns, formerly of the Phillips Petroleum Company, has been named executive secretary of the Kansas Medical Society He will visit other state executive offices before opening his office in Wichita about August 1 Mr Munns was appointed at a meeting in Wichita, June 24 Creation of this position was authorized at the recent meeting of the state medical society

### KENTUCKY

**Pioneer Physicians Commemorated**—A reproduction of a pioneer cabin on which is mounted a memorial tablet bearing the names of twenty-seven pioneer physicians was dedicated at special ceremonies in the Pioneer Memorial State Park at Harrodsburg, June 21, by the Kentucky State Medical Association and the Kentucky Pioneer Memorial Association Dr Arthur T McCormack, Louisville, secretary of the state medical association, made the dedicatory address and four descendants of Dr Thomas Walker, said to have been the first explorer of Kentucky, unveiled the tablet At a banquet following the ceremonies Dr Irvin Abell, Louisville, presided and addresses were made, among others, by Drs Philip F Barbour, Louisville, on "The Pioneer Doctor," and Mrs Bartlett K Menefee, Covington, president of the woman's auxiliary of the state medical association, on "The Pioneer Doctor's Wife" The auxiliary will later fit the cabin as a replica of a pioneer physician's office, it was announced

**Society News**—Dr Claude T Wolfe, Louisville, addressed the McCracken County Medical Society at Paducah, May 23, on "Relation of Chronic Sinus Disease to Bronchial Disorders," and Dr Oscar O Miller, Louisville, "Nontuberculous Infections of the Upper Respiratory Tract"—Dr J Isfried Hofbauer, Cincinnati, addressed the Mason County Medical Association, Maysville, May 9, on "Early Diagnosis and Etiology of Uterine Carcinoma" Dr Alphonse R Vonderahe, Cincinnati, addressed the society at a special meeting, May 2, on diseases of the brain—At the annual meeting of the Southwestern Kentucky Medical Association in Paducah, May 5, speakers were Drs Willis C Campbell, Memphis, on "Ununited Fractures", Hollis E Johnson, Nashville, "Collapse Therapy in Pulmonary Tuberculosis" William T Black, Memphis, "Uterine Bleeding" John A Toomey, Cleveland, "Treatment of Acute Contagious Diseases," and Edward R Palmer, Louisville, "The Lesser Social Evil" Dr George W Crile, Cleveland made the banquet address—Dr Albert L Bass, Louisville, was chosen president of the Eye, Ear and Throat Section of the Kentucky State Medical Association at the annual meeting in May

### MARYLAND

**Personal**—An exhibition of rare medical manuscripts and old books, chiefly the works of Jewish physicians was recently on display at the Central Enoch Pratt Free Library, through the courtesy of Dr Harry Friedenwald, Baltimore, who has been a collector for thirty years—Dr Adolf Meyer, Henry Phipps professor of psychiatry, Johns Hopkins University School of Medicine, Baltimore was awarded the honorary degree of doctor of science by Yale University, June 21—Drs Daniel H and Lauretta E Kress, Takoma Park cele-

brated their golden wedding anniversary, July 9, 2,000 persons at whose birth Dr Lauretta Kress had officiated were invited to the reception and 500 were in attendance. Dr Lauretta Kress has assisted at 3,571 births during her career.

### MASSACHUSETTS

**Dr Shattuck Fined**—According to the *New England Journal of Medicine*, Dr Ray H Shattuck, Boston, was found guilty on five counts in the Dorchester District Court, June 28, on a charge of prescribing drugs not in good faith and not in the course of his professional practice. A fine of \$50 on each count was imposed. The case was appealed.

**Outbreak of Gastro-Intestinal Disorder**—About 600 persons suddenly became ill recently in Fitchburg. The water supply was investigated immediately. Since a CWA camp, employing about thirty men, was situated near the watershed of Overlook reservoir, which served most of the persons stricken, pollution from this source was suspected. Specimens taken from twenty-four workers at the camp were negative for typhoid, however. Analyses of the water showed the presence of B coli the first day. Subsequent analyses showed the reservoir to be free from the colon bacillus, and no more cases appeared after the third day. It was believed that heavy rains at the time contaminated the reservoir. No deaths were reported.

### MICHIGAN

**Physician Honored**—A reception was held for Dr and Mrs Will L Griffin, Shelby, May 26, as a mark of appreciation for his services. Of the 600 persons in attendance at the reception, it was stated that 500 had been born with the assistance of Dr Griffin. Infants and grandparents were among the guests.

**Upper Peninsula Meeting**—The thirty-seventh annual meeting of the Upper Peninsula Medical Society will be held under the auspices of the Gogebic County Medical Society at Ironwood, August 16-17. The following physicians will participate in the program, among others:

John L Garvey, Milwaukee, Differential Diagnosis of Common Neurologic Conditions as Met with in General Practice  
Stuart Pritchard, Battle Creek, A Ray Diagnosis of Chest Lesions  
John S Lundy and Ralph M. Tovell, Rochester, Minn., Indications and Technique of Blood Transfusions  
Walter A. Fansler, Minneapolis, Injection Treatment of Hemorrhoids  
Bert E. Hempstead, Rochester, Minn., Sinus Infection—Diagnosis and Treatment  
Charles L. Brown, Ann Arbor, Allergy in General Medicine  
Richard M. Hewitt, chief of publications Mayo Clinic, Rochester, Minn., Art of Writing Medical Papers

Five minute talks will be given at the evening session, Thursday, by Drs. John J. Walch, Escanaba, president of the society, Frederick C. Warnshuis, Grand Rapids, secretary, Michigan State Medical Society, Clyde C. Slemmons, Grand Rapids, state health commissioner, and George L. LeFevre, Muskegon, president of the state medical society. Dr. James D. Bruce, Ann Arbor, and Governor William Comstock will deliver addresses at this session. Entertainment has also been planned.

### MISSISSIPPI

**Graduates of Foreign Schools**—In accordance with a resolution adopted by the Mississippi State Board of Health, June 25, only graduates of grade A medical schools of the United States and Canada will be permitted to take the examination for license to practice medicine in the state, and only graduates of grades A and B medical colleges of the United States and Canada will be granted license by reciprocity. The resolution further provides that any graduate of a foreign school making application for license, either by examination or by reciprocity, must show proof from the Council on Medical Education and Hospitals of the American Medical Association that his premedical training and medical education are equivalent to the standards of the Council. Even then the resolution states, his application may be accepted or rejected by the Mississippi State Board of Health.

### MISSOURI

**Precautions for Infantile Paralysis Epidemic**—A conference was called by the director of health of Kansas City recently to consider precautions to be taken should infantile paralysis occur in the city. According to the *Jackson County Medical Journal*, all private hospitals are urged to have wards or wings set aside for the care of infantile paralysis patients or suspects. In these wards the precautions to be adopted are those usually followed in typhoid isolation. Infantile paralysis patients admitted to the Kansas City General Hospital in the

last five years are being asked if they will be available for supplies of blood. While no serum or blood will be distributed through the general hospital, it will prepare a list of possible donors.

### NEW JERSEY

**Physician Honored**—Dr Herbert W. Foster, Montclair, was guest of honor at a dinner, May 23, at the Montclair Golf Club, observing the twenty-fifth anniversary of the founding of the society known as Associated Physicians of Montclair and Vicinity. Dr Foster was the founder and first president of the society.

**Personal**—William L. Sampson, ChE, assistant professor of biologic sciences at Rutgers University College of Pharmacy, New Brunswick, has been appointed to the research staff of Merck and Company, Rahway. —Dr William J. Carrington, Atlantic City, was recently elected president of Kiwanis International.

**Society News**—The Society of Surgeons of New Jersey held its spring meeting at Mountainside Hospital, Montclair, May 16. Among others on the program were Drs. Toufick Nicola, Cedar Grove, who conducted an orthopedic clinic, Victor B. Seidler, Montclair, a thyroid clinic, John D. Moore, Bloomfield, a dry clinic on diseases of the eye, Meredith F. Campbell, Montclair, demonstration by roentgen rays of urologic conditions in children. Demonstrations and five minute talks were presented by the obstetric department under the direction of Dr. George B. Verbeck, Caldwell, and various other departments also demonstrated their work. Dr. Walter B. Mount, Montclair, was chairman of the program committee. —Dr. Robert F. Sterner, Cheltenham, Pa., addressed the Gloucester County Medical Society, Pitman, May 17, on disease of the gallbladder. —Dr. James Ewing, New York, addressed the Hudson County Medical Society, Jersey City, May 8, on cancer. —Dr. Frederick T. Van Beuren Jr., New York, addressed the Morris County Medical Society, Grey-stone Park, May 17, on "Relation of the Hospital to the Public."

### NEW YORK

**Society News**—Dr. George W. Crile, Cleveland, addressed the Medical Society of the County of Nassau, Mineola, May 29, on "Five Points in Surgery of the Gallbladder and Ducts."

**New Board of Health**—A new administration in Buffalo has appointed the following board of health: Drs. Carroll J. Roberts, chairman, Thew Wright, Edward E. Haley, Ambrose A. Maciejewski, and August Lascola.

### New York City

**Tuberculosis Worker Honored**—Two hundred friends of Dr. Dwight Clifford Martin, chief of the tuberculosis bureau of the New York City Department of Health, gave a dinner at the Hotel McAlpin, June 12, celebrating his twentieth anniversary in that position. Speakers who paid tribute to Dr. Martin were Drs. John L. Rice, James Alexander Miller, William H. Park, George G. Ornstein, and Herbert R. Edwards. Dr. Robert E. Plunkett, director of the division of tuberculosis, New York State Department of Health, was toastmaster.

**Personal**—Dr. G. Canby Robinson, director of the New York Hospital—Cornell Medical College Association, has been granted a year's leave of absence. Dr. Robinson has been in active charge of the building of the new medical center and reorganization of the two institutions during the past six years. —Dr. Walter A. Bastedo received the honorary degree of master of science at the annual commencement of the Philadelphia College of Pharmacy and Science, June 6. —A testimonial dinner was tendered to Dr. Edwin R. Fiske, chairman of the medical board of Kings County Hospital, by the medical staff and alumni of the hospital, April 26. Dr. Fiske has been associated with the hospital for thirty-three years. —Dr. Robert A. Fraser has been appointed chief medical director of the New York Life Insurance Company, to succeed Dr. Ernest H. Limes, who retired after forty-five years of service. —Dr. Horace S. Warner retired July 1 from the position of medical referee for the Aetna Life Insurance Company. He was appointed in 1905.

**Group Hospitalization Plan**—The state department of social welfare has approved an application for the establishment of a nonprofit corporation to organize and administer a group hospitalization plan among the voluntary hospitals of New York and its suburbs. The establishment of the corporation to be known as Associated Hospital Service of New York now depends on the obtaining of funds to put the plan into operation and maintain it for six months, the payments

of beneficiaries will provide the hospital benefits after that time Governor Lehman recently approved a bill amending the state insurance law to permit development of this plan, which is sponsored by the United Hospital Fund, comprising fifty-six voluntary hospitals. It is anticipated that about 100 hospitals will participate. The proposed association would be controlled by eleven directors elected annually by a voting membership comprising the presidents of the Hospital Conference of the City of New York, the Brooklyn Hospital Council, the five county medical societies of New York, the Medical Society of the State of New York and the trustees of the United Hospital Fund. The individual cost would be \$10 a year and the service would be available only to the insured person, not to his dependents, though dependents may be included later, it is said. The subscriber would be entitled to three weeks of semiprivate hospital care after a ten day waiting period immediately following the signing of the contract (this waiting period would not apply in case of accident) and ten months in obstetric cases. The subscription does not include fees for medical service. Admission to the hospital would be granted only on the recommendation of the subscriber's physician. The new legislation and the development of the group payment plan are the result of a study made by a special committee of the United Hospital Fund, of which Dr Sigismund S Goldwater, now city commissioner of hospitals, was chairman.

### NORTH CAROLINA

**Study of Maternal Mortality**—Adequate prenatal care for expectant mothers was indicated as the principal means by which maternal mortality may be reduced, in a study of 550 deaths attributed to puerperal causes made by the bureau of vital statistics of the state board of health. Inquiries of physicians and midwives brought adequate information concerning 334 deaths. Of 209 white women who died in 1933 from puerperal causes, 187 were attended by physicians. Of forty-four women who consulted a physician before the end of the fourth month of pregnancy, twenty-six sought aid because of alarming symptoms. Among the 125 Negro women who died, only nine went to physicians before the fourth month and seven of those were already ill. Therefore only twenty of the 334 saw a physician early in pregnancy and while still apparently in good health. Of the 334 maternal deaths, 114 were caused by puerperal albuminuria and eclampsia and 24 by other toxemias of pregnancy. Puerperal septicemia caused the second largest number of deaths, 51. According to this evidence it appears that in the vast majority of cases the medical profession has had no opportunity to give protection to mothers, the report concluded. The marked prevalence of toxemias of pregnancy revealed in this study demands an investigation of the cause as well as the prevention and treatment of this condition, it was urged in the report. Conferences of physicians and health officers were held in twelve sections of the state in the course of the study, culminating in a general conference in Raleigh, March 26. All phases of medical care of prospective and actual mothers and of infants were discussed. A committee composed of Drs Harry H Johnson, Lousburg, James Street Brewer, Roseboro, Forest M Houser, Cherryville, and Thomas Leshe Lee, Kinston, drew up a set of minimum standards of prenatal and postnatal care, dissemination of which throughout the state will, it is believed, contribute to the solution of this problem.

### OHIO

**Personal**—Dr Henry R O'Brien, Oberlin, resigned as health commissioner of Lorain County in May.—Dr James Angus Doull, professor of hygiene and public health, Western Reserve University School of Medicine, Cleveland, has been elected to honorary membership in the Royal Sanitary Institute of Great Britain.—Dr Charles R Pontius, Fremont, was guest of honor at a dinner given by the Sandusky County Medical Society at DeMars Point Club, June 19, in celebration of the fiftieth anniversary of his medical practice. Dr Charles J Wehr, Bellevue, secretary of the society, was toastmaster and the speakers were Dr Norris W Gillette, Toledo, and George B Smith, DDS, Fremont. Dr Pontius reviewed changes in medical practice during the past fifty years.

**Dr Bachmeyer Honored**—At the annual reunion of the Alumni Association of the University of Cincinnati College of Medicine, June 14, tribute was paid to Dr Arthur C Bachmeyer, who has resigned as dean of the college. Dr Martin H Fischer presented a silver coffee service to Dr Bachmeyer on behalf of his colleagues at the college and the Cincinnati General Hospital. Other speakers of the evening were President Raymond Walters of the university. Drs William M Doughty and Fred Heindol and the guest speaker, Dr David

Riesman, Philadelphia, who discussed "Medical Progress in One Generation." Dr Ben L Bryant was elected president of the association.

### OKLAHOMA

**Society News**—The Muskogee County Medical Society held a joint meeting with the society of Sebastian County, Ark., in Muskogee in May. Speakers were the following Fort Smith physicians: Drs Curtis H Kennedy, "The Decline of Prescription Writing", Clarence B Billingsley, "Management of Labor," and Davis W Goldstein, "Unusual Malignancies About the Face".—Drs John L Day and Carl T Steen of the Central Oklahoma State Hospital, Norman, addressed the Comanche County Medical Society, Lawton, May 10, on mental hygiene and manic depressive psychosis, respectively.—The Stephens County Medical Society sponsored a public meeting on cancer in Duncan, May 29, speakers were Drs Everett S Lain and Wendell M Long, Oklahoma City.

### PENNSYLVANIA

**Hospital News**—The ex-residents' society of the Abington Memorial Hospital, Abington, held its second annual meeting June 28. The day was devoted to medical and surgical clinics, followed by a banquet in the evening. Dr Paul M Kistler, Wayne, is secretary of the society.

**Society News**—The Pittsburgh Medical Forum held the first of a series of symposiums on medical economics, June 21. Speakers were Drs Samuel B Goodstone, on "Voluntary Health Insurance", Louis Lasday, "Compulsory Health Insurance" and Henry M Snitzer, "Dispensary Practice as It Affects Medical Economics".—Dr Pascal Brooke Bland, Philadelphia, was guest speaker at a meeting of the eleventh councilor district of the Medical Society of Pennsylvania at the Summit Hotel, near Uniontown, July 12, on "Intracranial Injuries of the New-Born from the Standpoint of the General Practitioner". Dr Moses Behrend, president-elect of the state medical society, discussed workmen's compensation.—Speakers before the Fayette County Medical Society, Uniontown, June 7, were Drs James E Van Gilder, on pernicious anemia, Arthur E Crow, appendicitis, and Robert H Jeffrey, inguinal hernia.—Dr Roy R Snowden, Pittsburgh, addressed the Cambria County Medical Society, Johnstown, July 13, on "Newer Conceptions of Hypertension and Nephritis". Dr Herbert P Leopold, Philadelphia, addressed the society, June 21, on "Acute Appendicitis—Its Surgical Significance and Mortality".—Drs William V Mullin, Cleveland, and Thomas B Holloway, Philadelphia, addressed the Western Pennsylvania Eye, Ear, Nose and Throat Society, May 17, on "Influence of Allergy on Rhinology" and "Ocular Manifestations of Certain Intracranial Basal Lesions," respectively.

### TEXAS

**Special Society Elections**—Drs Ramsey H Moore, Dallas, and Frank H Lancaster, Houston, were elected president and secretary, respectively, of the Texas Pediatric Society at the annual meeting in San Antonio, May 16. At the meeting of the Texas Neurological Society, May 14, Drs Guy F Witt, Dallas, and Wilmer L Allison, Fort Worth, were elected president and secretary, respectively. New officers of the Texas Dermatological Society, elected at the annual meeting, May 14, were Drs Cornelius F Lehman, San Antonio, president, and Everett R Seale, Houston, secretary. Dr Everett F Jones, Wichita Falls, was elected president of the Texas Railway Surgeons' Association at the annual meeting, May 14, and Dr Ross B Trigg, Fort Worth, secretary.

### VIRGINIA

**Site of Civil War Hospital Marked**—A bronze tablet was placed on a worn boulder on Chimborazo Hill in Richmond, May 26, marking the site of Chimborazo Hospital, said to have been the largest military hospital in the world during the Civil War. It consisted of 150 wooden buildings and cared for a total of 76,000 patients during the war. The commandant of the hospital was Dr James B McCaw, father of Brig Gen Walter D McCaw, for many years librarian of the Army Medical Library at Washington, D C. Dr Edgar Erskine Hume, present librarian, was to have delivered the address of the occasion on the history of the hospital. Dr Hume was unable to attend, but his address was read by Dr Greer Baughman, Richmond, and the tablet was unveiled by Mrs Dabney H Maury, a daughter of Dr James B McCaw. The memorial was placed by the Confederate Memorial Literary Society.

**Society News**—Dr Frank P Coleman, Stuarts Draft, addressed the quarterly meeting of the Augusta County Medi-

cal Association, Staunton, May 2, on treatment of internal hemorrhoids by injection—Drs John M T Finney and Thomas R Boggs, among others, addressed the Fredericksburg Medical Society, May 29, on acute conditions in the abdomen and fungous infections of the tongue, respectively. At this meeting the society had as guests members of the Piedmont, Loudon and Fauquier county medical societies, the Northern Neck Medical Society, medical officers stationed at Quantico and Dahlgren and at the Civilian Conservation Corps camps at Bloody Angle, Wilderness and Chancellorsville—Drs John A C Colston Baltimore, and Samuel F Driver, Troutville, addressed the Roanoke Academy of Medicine, May 7, on "Serum Treatment of Tularemia" and "Urologic Problems of Childhood," respectively—Dr Thomas P Sprunt, Baltimore, addressed the Lynchburg Academy of Medicine, June 4, on "Treatment of Common Types of Arthritis."

### WASHINGTON

**Society News**—Dr Ira R Watkins, Aberdeen, addressed the Grays Harbor County Medical Society, May 16, on fractures—Dr Arthur C Jones, Portland, presented a paper on "The Physiologic Basis of Physical Therapy" at a meeting of the Pierce County Medical Society, Tacoma, May 22—Drs Otis F Lamson, Seattle, and Souren H Tashjian, Seattle, addressed the Yakima County Medical Society, Yakima, May 14, on intrathoracic goiter and treatment of infections by nutrient broth, respectively—Speakers at a meeting of the Walla Walla Valley Medical Society Walla Walla May 10, were Drs Joseph P Brennan and Donald Wair, Pendleton on "Treatment of Tetanus" and "Toxic Psychosis in Use of Sedatives" respectively, and Drs Pius A Rohrer and Hale A Haven Seattle "Transurethral Resection" and "Neurologic and Surgical Aspects of Injuries to the Spine," respectively.

### GENERAL

**Society News**—Dr Henry Kennon Dunham, Cincinnati, was elected president of the National Tuberculosis Association at its recent annual meeting and Dr Charles J Hatfield, Philadelphia, was reelected secretary. The next annual session will be held at Saranac Lake, N Y.

**Automobile Fatalities Increase**—The bureau of the census, U S Department of Commerce, announced that eighty-six large cities in the United States reported 607 deaths from automobile accidents for the four weeks ended July 7 as compared with 570 for the four weeks ended July 8 1933. Of the total number 498 occurred within the corporate limits of cities. For the fifty-two week periods ended July 7, 1934, and July 8, 1933, the totals for all the cities were 8,697 and 7,794, which indicate a recent rate of 23.3 per hundred thousand of population as against an earlier rate of 20.9.

**Examinations in Dermatology and Syphilology**—The American Board of Dermatology and Syphilology will hold examinations at the annual meeting of the Southern Medical Association in San Antonio November 13-16, if there are enough applications to warrant the trip. The written examination for group B applicants will be held in centers throughout the country, October 1, and the oral examinations in group A and group B at San Antonio. Applications should be filed in the office of the secretary, Dr Clarence Guy Lane, 416 Marlborough, Boston, before August 20. Application blanks and other information should be obtained from Dr Lane.

**Physicians Named to U S Science Advisory Board**—New appointments to the U S Science Advisory Board include those of Dr Simon Flexner, director of the Rockefeller Institute for Medical Research New York, Dr Milton J Rosenau, Boston, Charles Wilder professor of preventive medicine and hygiene, Harvard School of Public Health, and Dr Thomas Parran Jr, Albany, health commissioner of the state of New York. Frank R Lillie, PhD professor of zoology and dean of the division of biological sciences University of Chicago, was also among those named to the board. The Science Advisory Board was created by President Roosevelt, July 31 1933 to aid him and his department heads in the conduct of research in the federal government. The board now has fifteen members.

### CORRECTION

**Staff of Bronx Hospital**—In a recent article published in the department of THE JOURNAL devoted to the Council on Physical Therapy it was stated that Dr Luttinger was a member of the staff of the Bronx Hospital, New York. The superintendent of that hospital writes to say that Dr Luttinger is not connected with that hospital.

### The Tax on Cod Liver Oil

It was reported previously (THE JOURNAL, Oct 8, 1932, p 1275) that one result of the Ottawa conference was increased duties on foreign imports of certain drugs, notably cod liver oil, honey and linseed. What was said in the markets about honey and linseed, according to the *Lancet*, was "hardly audible above the noise made about the increase of duty on foreign cod liver oil." This was done to please Newfoundland and applied mainly to Norwegian cod liver oil. It was pointed out at the time that nearly all the Newfoundland cod liver oil was consumed in the United States and that Britain depended on Norway for the main supply. The increased price brought about by the duty would enable Newfoundland to send her oil across the Atlantic and get more for it. The diminished supply for the United States would also increase the price there and enable Norway to send its oil, excluded from Britain across the Atlantic. Thus the fundamental flaw of protection—the turning of industry from natural into artificial channels—is demonstrated in the result: dearer oil for everybody and two unnecessary journeys across the Atlantic.

Another evil of the mistaken Ottawa policy is now shown in a letter to the *Times* from an exporter of cod liver oil, who points out that the duty on cod liver oil was intended primarily to assist the sale of the Newfoundland oil. But there is considerable trade done in importing the Norwegian oil in bulk and reexporting it in bottles to the Far East. The margin of profit in this trade is small, but its importance lies in the fact that many general orders from wholesale dealers in the drug trade include cod liver oil, and if the oil cannot be obtained from the English dealers at competitive prices the general order goes elsewhere. The duty of 32 cents per gallon on the oil makes it impossible to compete with other nations. This exporter has been forced to raise the price. In spite of an advertising campaign abroad where his brand of oil is well known, his sales have gone rapidly down. This has been accompanied by a loss of general business, though exceptional efforts were made to retain it. Employment suffers accordingly and British ships lose freight. Perhaps, as in the case of the insulin tax, our protectionist government will give way after doing much mischief.

### Making Motor Cars Less Noisy

The efforts to mitigate the noise evil have been described in previous letters. In the *Times* Lord Horder, chairman of the committee of the Anti-Noise League, calls attention to an amendment to the road traffic bill, which is strongly supported by the league. Under the road traffic act of 1930, the minister of transport made a regulation that every vehicle propelled by internal combustion engine should have a silencer for reducing the noise of the exhaust. But this regulation is ignored by the manufacturers of many motorcycles and some of the most popular sports cars. One of the manufacturers of silencers publicly admitted that he supplies "partial silencers" not because of any difficulty, mechanical or economic, in supplying efficient ones, but because purchasers demand unnecessary noise. They cannot be punished for doing so as the liability for noncompliance with the regulation arises only in those using the road. As to these experience has shown that magistrates are unwilling to punish those who merely use the vehicle as sold to them. The proposed amendment will make it unlawful to sell a vehicle of which the use on the road would be unlawful. When the amendment was moved in the house of commons, the

government, while expressing sympathy with its object, was unable to accept it, as its enforcement was considered practically impossible. But the government stated that it is consulting the department of scientific research and the National Physical Laboratory and asking them to look into the scientific aspect of the silencing of automobiles to see whether it would not be possible to make a regulation dealing with the user that would be more precise and easier to apply. Voluntary cooperation is also being sought with the automobile manufacturers. The amendment was withdrawn.

### The Prevention of Tuberculosis

The twentieth annual conference of the Society for the Prevention of Tuberculosis was held in London under the chairmanship of Sir Robert Philip. Sir Hilton Young, minister of health, paid a tribute to the work of the association since its inauguration in 1898 in instructing the public. Lord Astor, chairman of the departmental committee on tuberculosis, whose recommendations for the control of the disease, made twenty-one years ago, were the basis of subsequent progress, said that the outbreak of the war prevented them from coming into effect until 1919. Some of the decline in the tuberculosis of children he attributed to dealing with the problem of tuberculous milk.

Dr A. S. Macnalty, senior medical officer to the Ministry of Health, said that the chief problem in the past had been residential institutional accommodation but that now it was instruction of the public in the early symptoms of tuberculosis. The state had realized the factors favoring the disease, such as certain occupations, malnutrition, overcrowding and bad sanitation. Antituberculous work was now an integral part of public health, and the health officer could coordinate all the branches of prevention. More attention need to be paid to the examination of contacts and the provision of adequate after-care for arrested cases, with special reference to home surroundings and occupation.

Dr N. D. Bardswell, principal assistant medical officer to the London County Council, reviewed the progress made in London, where there is a central authority that provides residential treatment and thirty-five dispensaries linked up with the neighboring hospitals. A decline of nearly 40 per cent in pulmonary tuberculosis and over 75 per cent in nonpulmonary tuberculosis in twenty-one years had resulted. Although other factors were concerned and the falling incidence had been in progress since 1875, he felt that the work in prevention had materially contributed. The popularity of tuberculin treatment had gradually faded away and today was not seriously considered as a cure. Children living in conditions of danger of infection, or those who would be left unattended if the woman of the household went away for treatment, were boarded out.

### THE TUBERCULOSIS DISPENSARY

Dr G. Lissant Cox, central tuberculosis officer for Lancashire, said that the dispensary unit should work in unison with the institutional unit and that lack of this unity was the cause of much ineffective work. The tuberculosis officer should be at the same time a medical superintendent visiting or resident, and the medical superintendent should be in part a tuberculosis dispensary officer. Dispensary units had been much too small; they should serve a population of 200,000 in a rural and 300,000 in an urban district. In the discussion it was suggested that dispensaries should be attached to the teaching and public assistance hospitals and that tuberculosis officers should look forward to clinical rather than to administrative preferment.

### RESIDENTIAL INSTITUTIONS

Dr James Watt, medical superintendent of King George V Sanatorium, pointed out the great change brought about in residential institutions by radiography and collapse therapy,

thoracoscopy and the electrical cutting of adhesions. The sanatorium no longer resembled a convalescent home but a hospital.

Dr J. B. McDougall, medical director of British Legion Village, said that too much attention had been paid to the medical aspects of tuberculosis and too little to the economic. After-care committees failed for lack of financial support. The village settlement, as exemplified at Papworth, sold annually about \$1,000,000 of goods to the public, and \$250,000 was paid in wages to ex-patients. This might be regarded as ideal, but local authorities were deterred by financial considerations from establishing them. In the village settlement the family as a whole was cared for as carefully as the patient.

### AFTER-CARE

Miss Edith McGaw, honorary secretary to the Paddington Tuberculosis Dispensary, insisted that the care committee was an integral part of the tuberculosis dispensary. Yet there were only 150 care committees to the 750 dispensaries in the country. Tuberculosis was a many-sided social problem as well as a medical one. The family, not the individual patient, was the unit. The rehabilitation of the patient's home was as essential as the treatment of its members. The members of care committees could give help in the homes by instruction in cooking, advice regarding the amount of clothing desirable, and other matters. Assistance was often needed as regards home work, and handicraft classes should be encouraged.

### The Sterilization of Mental Defectives

The Mental Hospitals Committee of the London County Council has decided by a majority to recommend that mental defectives be permitted to offer themselves voluntarily for sterilization. The decision followed consideration of a recommendation of the Ministry of Health to the committee. It is understood that sterilization is to be applied only to patients who are likely again to be able to take their places in the community after leaving institutions and to transmit their defects. The vote was 23 to 11. For the first time since the socialists have obtained control of the London County Council, the party whips were taken off and so the vote was a free one.

### PARIS

### Dangers of Barbituric Acid Derivatives

Injections of strychnine to combat the toxic effects of barbituric acid derivatives, according to the Idd method, are accepted today in France as the only remedy offering any chances of success. The conclusion has been reached that there is a pharmacodynamic antagonism between strychnine and the barbiturates. Carriere, Huriez and Villoguet have experimented on animals, examining the lesions found at necropsies, and have raised a protest against the commonly accepted view. In experimental animals they discovered grave lesions of the kidney, the liver, the lung and the nerve centers, which no medicinal action eliminated. Carriere does not think there is an antagonism between strychnine and the barbiturates. On the contrary, he found that poisonings due to the two substances may be superimposed each of the substances exerting totally different effects on the nervous system. Furthermore, the good results ascribed to the Idd method are far from constant. There are a number of failures, which are not due solely to the dose of ingested toxin but partly to the peculiar predisposition of the subject. In case of suicide due to an overdose, the subject though often an addict to barbiturates, may develop hepatic lesions that lower resistance and which strychnine will not overcome. In cases in which strychnine has given good results, it is never the only remedy.

used, often the practitioner resorts to venesection, injections of serum with dextrose, epinephrine, camphorated oil and inhalations of oxygen. Carriere states that one may use strychnine, since no remedy should be neglected in the presence of the danger of death, but it should not be relied on or be the sole remedy. The practitioner must use conjointly all other remedies and not be surprised if they fail, especially if he is dealing with persons addicted to barbiturates. In operating on animals, Carriere secured excellent results with intravenous injections of coramin and a 30 per cent solution of alcohol. He recommends applying this remedy to man.

#### The General Association of Physicians of France

The Association generale des medecine de France, which is not concerned with scientific questions but rather with professional problems and the providing of mutual aid for physicians, held recently its seventy-second general assembly. The association has vast resources derived from numerous bequests of benefactors. It provides places of retirement for its aged members no longer able to practice their profession, and aid for physicians who are bereft of resources (or cares for their widows), even though they are not subscribing members of the association. The general secretary, Dr. Lutaud, announced that the association is prosperous. He described the services that it renders and emphasized the value of preserving close relations with the medical syndicates. Formerly there was a feeling of rivalry between the association and the syndicates, but today the relations are cordial. The association has relinquished to the medical syndicates, whose meetings are more frequent, many questions that formerly overloaded its program and which it was not in as good a position to solve as were the syndicates. The secretary, in concluding his remarks, advised all physicians of France to be loyal to both the association and the local syndicates. The assembly adopted a resolution in favor of suppressing the special tax termed "patente," imposed on certain liberal professions (physicians and lawyers) and which, proportioned according to the amount of house rent paid by the taxpayer, without taking account of the relative family expenses, rests heavily on the profession. The assembly rejected the proposal of Perrin of Nancy, who suggested that this tax (patente) be applied also to physicians who are not engaged in actual practice but who occupy posts as directors of sanatoriums and various institutions and are now exempted.

#### The Forty-Seventh Congress of Ophthalmology

The Congress ophthalmologie de Paris, always well attended, was the occasion for presenting a wide range of topics, which give a survey of the present status of ophthalmology. In addition, a single main topic was treated in a paper presented by Cherod and Nataf of Tunis on 'Biopsy of the Normal and Pathologic Conjunctiva'. Examination with the slit lamp facilitates the study of microscopic phenomena in living subjects. In this manner one may study the mechanism of the formation of lesions of the cornea, iris and crystalline lens and even of the vitreous body, the reactions of the tissues, the effects of traumatism and infection, and the development of local vascularization and lymphoid elements. The authors think that this marks a new era in knowledge of the mechanism of various lesions of the eye. In addition Mr. Kalt of Paris described his operative procedure for senile cataract. He extracts the cataract within its capsule. Mr. Terson of Paris discussed hypertension in glaucoma. Mr. Lacat emphasized the inefficiency of iridectomy in the glaucomatous manifestations of certain forms of choroiditis. Mr. Trantas of Athens called attention to the high frequency of glaucoma in Greece and in Turkey. Jandelize, Baudelot and Gauzt (Nancy) have treated retinal detachment, without visible laceration by diathermocoagulation. Mr. Genet of Lyons reported the results

of diathermic applications to retinal cicatrices following detachment. Mr. Magitot of Paris called attention to the amelioration secured by means of pericarotid sympathectomy in certain degenerative lesions of the retina and the optic nerve. Mr. Baillart described the role of vascular spasms in diseases of the eye. Mr. Villard of Montpellier discussed the eye dangers peculiar to each type of sport. Among other foreign speakers were Arruga of Barcelona, Poyales and Moreno of Madrid, Amat of Madrid, Marquez of Madrid, Goun of Lausanne, Fritz of Mons, Borel of Neufchatel, François of Charleroi, Kapuscinski of Posnan, and Van der Stacten and Appermans of Louvain.

#### The Institute of Legal Medicine at Lille

At Lille the opening of the new institute of legal medicine, recently erected, was the occasion of a congress presided over by Professor Leclercq, director of the institute, which was largely attended by medicolegalists of the north of France and by delegations of specialists from Paris and foreign countries. Balthazard Guibert and Piedelievre of Paris, Firket of Liege, Zangger of Zurich, Tullio and Salvatore Diez of Rome, Lattes of Pavia, Georgiades of Athens, Ribero and Ciala of Rio de Janeiro, Stanesco of Bucharest, and Amot and Vervaeck of Brussels. The arrangements and equipment of the institute enable investigators to devote themselves not only to traditional legal medicine but also to its newer branches: criminal anthropology, research on penitentiaries, occupational medicine and psychopathologic examinations of delinquents. The institute will serve not only as a research center but also as a school for the training of medicolegalists. In the opening address, Professor Leclercq stressed the evolution of legal medicine and the importance of psychophysiologic examination of delinquents. Papers were presented on the contradictory results of expert mental examinations, on social defense and on criminal prophylaxis, and the like by Professors Raviart and Vulliam of Lille, Professor di Tullio of Rome (a pupil of Lombroso), Professor Balthazard of Paris, and Professor Vervaeck of Brussels.

#### BERLIN

(From Our Regular Correspondent)

June 4, 1934

#### Meeting of the German Roentgen Society

The Deutsche Röntgengesellschaft has been reorganized in accordance with the "leader" principle. The new director is Frik of Berlin. At a session of the society in Baden-Baden, April 14-15, Forsell of Stockholm presented a paper on "The Motor Mechanism of the Gastric Mucosa." He explained his basis for the theory he advanced eleven years ago to the effect that the surface of the gastric mucosa is characterized by changeable features and is formed by the muscularis mucosae (under the influence of the autonomic nervous system). He presented new evidence in support of his belief. The gastric mucosa forms channels and digestive nooks, in which solid pieces of food are retained. The vessels of the mucosa may become distended but cannot form rugae.

In an address "The Real and the Apparent in Roentgenograms," H. Franke of Berlin discussed the many deceptions that may arise in the interpretation of roentgenograms, through technical and physical errors, faulty delineation shadows, errors of amplifying screens and the treatment of films, and also through optical illusions, quite apart from the erroneous interpretations due to lack of experience and critical judgment. He emphasized that there is no common agreement as to what roentgen apparatus and tubes are best for certain purposes.

A number of papers dealt with roentgen kymography, which is superior to kinematography. It enables the examiner to obtain a graphic registration of motions and their course in

point of time. In the heart, synchronous registrations of the arterial pulse, the apical beat and the heart margin pulsations, together with a time analysis of the heart cycle, may be made. By means of kymography, the value of which was emphasized by the papers of Stumpf and Bickenbach of Munich, the cardiac apex is more easily located in connection with heart measurement, likewise the dividing line between the left ventricle and the left auricle and pulmonary arteries. Kymography aids also in the diagnosis of aortic defects, likewise in the differential diagnosis between aneurysm and tumor. The method is useful in dealing with the kidneys, ureters and stomach, it likewise gives information on the position and extent of adhesions and contraction of lungs in connection with collapse treatment of pulmonary tuberculosis, also in cardiac infarct.

A paper was presented by Fichera of Milan on his method of biologic treatment of cancer, which is the result of years of study on the biology of cancer in connection with clinical observations. The fact that many organs seldom develop cancer metastases, that their absence furthers the growth of tumors and that their implantation checks such growth was utilized. Logical application of such biologic observations, together with carefully planned imitation of natural defense processes, led to the injection of corresponding organ extracts, with the result that, of 160 inoperable tumors, 9 per cent retrogressed entirely and 8 per cent partially. By simultaneous application of radiologic therapy the effects are improved, since the action of the two different agents on the tumor tissue has much in common. By means of microscopic sections, Fichera showed the retrogression in the tumors during the treatment. During the discussion various opinions were expressed, and some were not favorable. In any event, more observations should be made.

Other papers dealt with the cancer problem, partly with statistics and partly with the results of irradiation in carcinomas of various organs. Technical questions were considered and observations in several cases were reported. The outcome of short wave therapy in a number of cases was announced. In contrast with former conditions, new apparatus has achieved good results even in inflammatory gynecologic disorders. Specific effects of short waves in the treatment of malignant tumors were denied and such apparent effects were explained as due to the action of heat.

#### The Effects of Nicotine

In connection with the success of the Deutsches Tabakforschungsinstitut in Forchheim, with the cultivation of tobacco plants with a reduced nicotine content, it is time for the medical profession to raise the question as to whether nicotine should not be renounced in the interest of public health. Dr. Stroo- mann discussed these questions before the medical society of Frankfurt-on-Main. Nicotine is a poison which, acting on the vegetative nervous system, exerts an irritative and also stimulative effect before it paralyzes. If the right kind of tobacco is selected and the method of smoking is correct (no inhaling, observance of proper intervals, discarding of the stump, in which a 11-13 per cent enrichment occurs), the stimulative effects of nicotine will usually predominate over the narcotic effects, for example, smoking often promotes digestion, through the excretion of epinephrine it may possibly have a stimulative influence on the circulation through its psychic influence it may affect work output, concentration, mood and fatigue. The abstinence manifestations (languor, irritability, restlessness, headache, indigestion) are usually of a moderate type, genuine addiction is extremely rare. That smoking is habit forming has not been proved by animal experimentation although it has been shown to be probable. In the detoxication process the liver plays a special part. Of the injuries resulting from immoderate and improper smoking cardiac and vascular disorders are important. Severe damage to the coronary vessels,

which occurs clinically in about 28 per cent of smokers, has received a satisfactory explanation through Professor Reim of Gottingen. In the dog, nicotine produces an unequivocal marked vasoconstriction of the coronary vessels. Heavy doses occasion the well known increase of blood pressure, with simultaneous increase of the heart beat. That signifies, however, stimulation of the heart to make undue efforts, while, at the same time, the coronary arteries are suppressed—a catastrophe. Coronary infarct of purely vasomotor origin is assumed. In association with nicotine gangrene in a juvenile smoker, he found a certain constitutional narrowing and thinness in the walls of the vessels. A sure explanation of the predominant injury of vessels of the extremities and the viscera cannot be given as yet. In any event, importance attaches to the condition of the corresponding sympathetic ganglions. Spastic injury over a long period, due to nicotine, may prepare the way for later anatomic narrowing of the vessels. Increase of blood pressure in man as a result of nicotine must not be over-emphasized. The transitory increase of pressure due to excretion of epinephrine as a result of nicotine must be regarded as more important. Frequent occurrence of bronchial carcinoma in smokers appears possible. Gastritis with superacidity and supersecretion is frequent in association with acute abuse of smoking, in chronic abuse of tobacco, an acidity occurs. Cases of ulcers in juvenile smokers appear to be assured. The increase of blood sugar resulting from nicotine in diabetic persons is so slight that it has no practical value. Increase of basal metabolism through action on the thyroid is assumed clinically. The enjoyment of smoking lies chiefly in the taste and secondarily in the odor, the influence of ocular perception is overestimated. Acute poisonings due to nicotine have increased in recent years, since high concentrates of nicotine can be bought as insecticide, without a "poison" label.

#### Nutritional Treatment of Diabetes Mellitus

According to Naunyn and others, the principal task in the dietetic treatment of diabetes mellitus lay in a restriction of the carbohydrates and proteins, with occasionally generous additions of fat. Stolte, however, gives diabetic children carbohydrates up to normal requirements, comparatively little fat and an average quantity of proteins, but at the same time, insulin until aglycosuria is established. A similar procedure in dealing with adult diabetic patients, as W. Ercklentz of Breslau now reports, showed the favorable effects of this diet. The notable increase in the carbohydrates requires no proportionate increase of insulin, for example, patients who, with 50 Gm of carbohydrates, required 70 units of insulin, needed only 120 units when the carbohydrate was increased to 500 Gm. Thus far the following results have been attained. The sharp increase of carbohydrates is highly appreciated by the patient and is well borne, the rise in the blood sugar is balanced by an increase of insulin. The amount of insulin required for the elaboration of the increased quantity of carbohydrates is much less than would be expected from the amount of insulin required with the ingestion of the smaller quantities of carbohydrates. Following a prolonged administration of large quantities of carbohydrates, a gradual improvement in the state of metabolism becomes evident, which enables the practitioner to reduce materially the insulin dosage and occasionally to omit it entirely for a time.

#### Deaths in the Early Morning Hours

The observation that a high percentage of moribund persons die during the early morning hours has been inquired into by Dr. Jusatz and Dr. Eckhardt, of the hygienic institute at the University of Marburg, and the results of their inquiry were reported recently in the *Münchener medizinische Nachrichten*. A comparison was made between 3,294 deaths occurring during

the past six years in Marburg, on the one hand, and 3,769 deaths from Rostock and 1,444 deaths from Kovno (Lithuania). Suicides and deaths due to accident were not considered. In all the statistics there was a general agreement that the greatest number of deaths occurred in the early morning hours, while the smallest number at night is around midnight. The same course of events occurred ninety years ago. The smallest number of deaths during the twenty-four hours occurs at noon—in Rostock around 11 o'clock. In the afternoon there is considerable variation in the curves. An explanation of the connection between the daily course of mortality and physically measurable periods of time would be of great biologic interest. It may be noted with reference to the daily fluctuations of electrical conductivity that the maximums lie between 4 and 5 o'clock in the morning and the minimums in the midday hours.

#### A New Outbreak of Psittacosis

In the *Reichsgesundheitsblatt*, Prof. J. Fortner and R. Pfaffenberger report from the Institut für Infektionskrankheiten Robert Koch, Berlin, a new outbreak of psittacosis. Since the beginning of 1934 Germany has had a recrudescence of cases of psittacosis in man. According to reports sent to the Robert Koch Institute there have been seventeen familial outbreaks so far this year, fourteen of which were in Berlin. The total number of cases is forty-two, ten of which were fatal. In seventeen instances, investigators found the causative agent in parrots that had recently been furnished by bird dealers. The birds that carried the virus were all apparently well except one.

#### ITALY

(From Our Regular Correspondent)

May 15, 1934

#### The Blood Sugar Curve in Mental Diseases

Dr. Telatin has made a comparative study of the blood sugar and of the sugar of the spinal fluid following the administration of 1 mg. of epinephrine, in mental patients. Discussing before the Accademia delle scienze mediche e naturali di Ferrara his results, the author, who made use of the Folin-Wu procedure, called attention to a characteristic spinal fluid sugar curve of dementia praecox. An ascending curve was observed in all patients studied. In epileptic patients the curve is almost constantly ascending and without interruptions. In dementia praecox patients however, Telatin found constantly a negative curve, and as the blood sugar was increased the spinal fluid sugar was lowered, the lowest value being observed at the moment when the blood sugar reached its highest point. From that moment the spinal fluid sugar increased slowly, until it reached and exceeded the index that it presented at the beginning of the test.

#### The Academy of Medicine of Turin

The recent session of the Accademia di medicina di Torino opened with Professor Tirelli in the chair. Angioleri recalled the various forms of constitutional and hereditary hemorrhagic diathesis and described the fundamental characteristics of Osler's disease, or familial hemorrhagic angiomatosis. These characteristics consist in the transmission of the morbid syndrome as the expression of a dominant character, in the appearance of mucous and cutaneous hemorrhages, or in the presence on the skin or on the mucosae of smooth angiomatous lesions of various size. At the base of the symptomatology lie certain lesions of the connective tissue and of the mesenchymal apparatus of the skin. Also the blood vessels appear changed—so much so as sometimes to appear constituted solely of endothelium which is supported by tissue of normal quality. The etiology of this rare form of familial hemorrhagic diathesis is unknown, and the treatment is symptomatic.

Pioletti described the results of the administration of arsphenamines in large doses to persons overnourished with carbohydrates and subjected to the action of insulin. This method produces a notable increase in the tolerance of the organism for arsenical therapy. The speaker interprets the action of the insulin, and of many other substances that serve the same purpose, as an action designed to save the protein substances of the liver, on which devolves the normal antitoxic function.

Bobbio reported the results of researches on the permeability of the lymph glands invaded by tuberculosis. As a result of a tuberculous invasion, one observes in the lymph glands changes in the lymphatic circulation, and the persistence of a certain degree of permeability is demonstrated by the absorption of India ink injected into adjacent areas. The entity of the lymphatic current is diminished in relation to the diminution of the functioning lymphatic tissue, and the velocity of the current is diminished by the obstruction occasioned by the discontinuity that is created in the lymph paths through the irregular invasion by the tuberculous process.

Battistini and Herlitzka announced the results of studies on the behavior of the blood sugar and the urinary sugar following subcutaneous injections of phlorhizin, whether with a burdening test or otherwise. In healthy persons they always found that the urinary sugar varied within wide limits and independent of the blood sugar values, which shows that phlorhizin induces a notable increase in the difference between the capillary and the venous values. This leads to the supposition that phlorhizin increases the fixation potency of the peripheral tissues through the dextrose.

#### Recent Developments in the Anemias

Dr. Di Guglielmo presented recently before the Società medico-chirurgica di Catania a communication on the anemias. Since the almost complete disappearance of chlorosis, there remain in the large group of anemias only two types that are not secondary: pernicious anemia and essential hypochromic anemia. The last mentioned type, which has been known only a few years, is characterized by hypochromia, microcytosis and gastric achylia or anachlorhydria. Pernicious anemia and essential hypochromic anemia, while entirely different from the hematologic point of view, have gastric achylia in common, which, however, is to be regarded as also of a different nature, for the action directed against pernicious anemia, which is secured with meat predigested in vitro by the gastric juice of a patient with essential hypochromic anemia, is completely lacking when one uses the gastric juice of a patient with pernicious anemia. Hence, in the present state of knowledge of the subject it can only be stated that the two morbid processes belong to the group of achylic anemias, which must be studied now more profoundly.

Essential hypochromic anemia, in contradistinction to the pernicious type, is not affected by the action of liver preparations, although it may be cured by the use of iron in heavy doses orally.

#### Use of Therapeutic Products

The Public Health Service recently sent a circular letter to the prefects establishing rules governing the application to man of new therapeutic products not yet offered for sale on the public market. Heretofore it has been held by many that such application might be made, provided it was done by a physician, on his own responsibility. According to the new rulings, the prohibition of sale to the public of medicines and preparations to which are attributed specific curative and prophylactic properties presupposes also the prohibition of free application to man until there has been secured the registration prescribed by the regulations pertaining to serums, vaccines and medicinal specialties, and until the formula and the mode of employment

have been announced and approved. Authorization is to be intrusted to the minister of the interior. When it is a question of remedies or treatments that are to be kept secret, the authorization is dependent on the conditions that the application be gratuitous, be effected in public institutions on the written consent of the patient, and that a report be sent to the provincial health officer on the results secured.

The circular letter contained also regulations concerning the advertising of remedies for the prevention and treatment of disease. The insertion in newspapers of notices or correspondence referring to special procedures for the prompt and radical treatment of malignant tumors, tuberculosis, venereal infections and all those diseases for which no quick cure has as yet been discovered is prohibited. The proper place for scientific communications of this type is the medical congress and the medical journals.

#### Pathology of the Intervertebral Disks

A recent meeting of the Società Piemontese di chirurgia was devoted entirely to the pathologic aspects of the intervertebral disks.

Camera took up the question of the pathogenesis of the symptom complex. According to the speaker, so-called kyphosis of adolescents should be regarded as an epiphyseal dystrophy. The calcification of the nucleus pulposus is not to be regarded as a pathogenetic peculiarity but must be considered as an expression of a local, changed calcium metabolism due to the existence of an involvement of the disks.

Dogliotti reported his observations on 120 cases of spinal algias. Teneff reported his observations in cases in which there were lesions on an intervertebral disk between the fourth and fifth lumbar vertebrae and between the fifth vertebra and the sacrum, in which there was a frank monolateral peripheral sciatic symptomatology of funicular origin but without any symptoms of lumbago arthritis. He believes that in such cases the pathogenesis of the ischialgia is in mechanical, circulatory or inflammatory changes in the intervertebral foramina following changes in the intervertebral disks.

The same speaker, on examination of 600 roentgenograms of the spinal columns of patients who presented an intervertebral pain symptomatology, found a case of hernia intraspinalis of the disk.

A case of lesions of the intervertebral disk due to gonococcal infection was described by Lucca. He observed in a woman aged 73 a lesion that he regarded as a calcified hernia of the body of a vertebra.

### Marriages

ARCHIBALD CORY RANDOLPH to Mrs. Rebecca Dulane McElhone, both of Upperville, Va., June 2.

JEROME J. BREDALL, Perryville, Mo., to Miss Mary Katherine Lacey of St. Louis, June 30.

EDWIN JAMES RENNELL, Manistec, Mich., to Miss Mary Foster of Traverse City, June 2.

JONAS B. RAYMAN, Toledo, Ohio, to Miss Lila Tobin of Miami Beach, Fla., May 22.

JOHN B. TUTTLE to Mrs. Minnie H. Buchanan, both of Craigsville, Va., June 7.

SIMON YOUNG SALTMAN, Chicago, to Miss Goldye Lazarus of Brooklyn, July 1.

NORMAN E. FISHER, Toledo, Ohio, to Miss Jeanne Littwitz of Dayton, May 30.

SIMON S. RUBIN, Chicago, to Miss Anna Chesney of Philadelphia, May 25.

HOWARD G. BRUSS to Miss Catherine White, both of Toledo, May 30.

DARRELL C. CRAIN JR., Washington, D. C., to Miss Louise Moore, July 12.

### Deaths

Robert Gibson Eccles, Brooklyn, Long Island College Hospital, Brooklyn, 1881, member of the American Association of Anatomists, professor of organic chemistry and dean, Brooklyn College of Pharmacy, at one time chemist to the United States Department of Indian Affairs, past president of the New York Pharmaceutical Association and the chemical section of the Brooklyn Institute of Arts and Sciences, author of "Food Preservatives, Their Advantage and Proper Use," and others, also monographs on medicine, pharmacy and scientific subjects, aged 86, died, June 9, in St. John's Hospital of injuries received when he was struck by a street car.

Frank Anderson Overbay, New Orleans, Tulane University of Louisiana School of Medicine, New Orleans, 1914, assistant professor of ophthalmology, Louisiana State University Medical Center, fellow of the American College of Surgeons, visiting ophthalmologist to the Touro Infirmary, 1914-1918, senior ophthalmologist to the Presbyterian Hospital 1918-1924, senior ophthalmologist to the French Hospital, senior associate ophthalmologist to the Southern Baptist Hospital and visiting ophthalmologist to the Charity Hospital, aged 51, died suddenly, May 10, of heart disease.

Fred Albert Simmons, Boston, Columbia University College of Physicians and Surgeons, New York, 1903, member of the Massachusetts Medical Society and the New England Otolaryngological and Laryngological Society, at one time instructor in otology, Harvard University Medical School, veteran of the Spanish-American and World wars, formerly on the staffs of the Massachusetts General Hospital and Massachusetts Eye and Ear Infirmary, aged 56, died May 27, of hypertension, arteriosclerosis and dissecting aneurysm of the aorta.

Herman Campbell Stevens, Elyria, Ohio, Rush Medical College, Chicago, 1913, past president of the Lorain County Medical Society, research fellow in experimental medicine, Western Reserve University, Cleveland, since 1928, physician for the American Red Cross during the World War, assistant professor of neurology, University of Illinois College of Medicine, Chicago, 1918-1919, aged 55, formerly on the staffs of St. Luke's Hospital, Cleveland, and the Elyria Memorial Hospital, where he died, May 27, of pneumonia.

Chester Allen Amos, Alexandria, Va., University of Virginia Department of Medicine, Charlottesville, 1917, formerly professor of histology and embryology, Georgetown University School of Medicine, Washington, D. C., served during the World War on the staff of the Alexandria Hospital, aged 41, was killed, June 10, when the automobile in which he was driving was struck by a train.

Edward Danforth Keyes, Winona, Minn., Rush Medical College, Chicago, 1885, president of the American Association of Railway Surgeons, member of the Minnesota State Medical Association, past president of the Winona County Medical Society, formerly health officer of Winona for many years on the staff of the Winona General Hospital, aged 75, died, May 21, of cerebral thrombosis.

Hjalmar Ostrom, Quincy, Mass., John A. Creighton Medical College, Omaha, 1911, missionary to the Belgian Congo for seventeen years representing the American Baptist Foreign Missionary Society, aged 52, died, May 24, in the New England Baptist Hospital, Boston, of peritonitis and hemorrhage, following subtotal gastrectomy.

Everett Augustin Lockett, Winston-Salem, N. C., University of Pennsylvania School of Medicine, Philadelphia, 1902, fellow of the American College of Surgeons, served during the World War, on the staffs of the City Memorial and North Carolina Baptist hospitals, aged 55, was found dead, June 26, of angina pectoris.

Nicholas Vincent Walsh, Staten Island, N. Y., Long Island College Hospital, Brooklyn, 1918, member of the Medical Society of the State of New York, on the staff of St. Vincent's Hospital, aged 45, died, May 25, at Deal Lake, N. J., of hypertension and heart disease.

Albert De Forest Wickett, Ann Arbor, Mich., University of Michigan Medical School, Ann Arbor, 1917, formerly assistant professor of internal medicine at his alma mater, on the staff of St. Joseph's Mercy Hospital, aged 44, died suddenly, May 1, of coronary thrombosis.

Harry Michael Hepperlen, Beatrice, Neb., Keokuk (Iowa) Medical College, 1891, Jefferson Medical College of Philadelphia, 1896, fellow of the American College of Surgeons, on the staff of the Lutheran Hospital, aged 66, died May 5, of carcinoma of the prostate.

Eugene Kneeland Smith, Lovelock, Nev., Medical Department of the University of California, San Francisco, 1904, served during the Spanish-American and World wars, formerly medical superintendent of the Lovelock Hospital, aged 54, was killed, May 16, in an automobile accident

Harry Arthur Vosburg Jr., Du Bois, Pa., Jefferson Medical College of Philadelphia, 1912, member of the Medical Society of the State of Pennsylvania, on the staffs of the Du Bois and Maple Avenue hospitals, aged 44, died, May 18, of acute hemorrhagic nephritis

Samuel Wellington Irving, New Britain, Conn., Yale University School of Medicine, New Haven, 1891, past president of the Hartford County Medical Society, aged 73, on the staff of the New Britain General Hospital, where he died, May 8, of coronary occlusion

Walter Baer Weidner, New York University of Pennsylvania School of Medicine, Philadelphia 1898 formerly on the staffs of the Sharon (Conn.) Hospital Flushing (N. Y.) and Nassau Hospital, Mineola, aged 60, hanged himself, June 22

William S. Davis, Detroit, Medical College of Ohio Cincinnati 1890, veteran of the Spanish-American War, at one time health commissioner of Vigo County, Indiana, aged 68, died, June 2, of cerebral embolism and chronic myocarditis

Frederick Rhinhart Dorn, Echo Ore, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1903, member of the Oregon State Medical Society, aged 63, died, April 4, of heart disease

Herman Bocken, Harlan Iowa, University of Nebraska College of Medicine, Omaha, 1911, past president of the Shelby County Medical Society county coroner, on the staff of the Harlan Hospital, aged 46, died, June 10, of pneumonia

Ernest Oliver Winship, New London, Conn., University of Vermont College of Medicine, Burlington, 1900 on the staff of the Lawrence and Memorial Associated Hospitals, aged 58, died, June 1, of carcinoma of the liver

Saul Steiner, New York University of Bucarest School of Medicine, Bucarest, Roumania, 1901 on the staffs of the Westside Hospital and Dispensary and the Broad Street Hospital, aged 62, died, June 10, of heart disease

David Edward Bowman, Toledo, Ohio University of Michigan Medical School, Ann Arbor, 1881 member of the Ohio State Medical Association, aged 77, died, June 21, of lobar pneumonia and intestinal obstruction

David Christian Batson, Birmingham Ala., University of Nashville (Tenn.) Medical Department 1905 member of the Medical Association of the State of Alabama aged 56, died May 17, of a self inflicted bullet wound

William H. Pallett, Crete, Neb., Kansas City (Mo.) Medical College, 1898, served during the World War for twenty-five years member of the school board, aged 63, died, June 19 of cerebral hemorrhage

John H. Reagan, San Antonio Texas (registered by Texas State Board of Medical Examiners, Act of 1907), member of the State Medical Association of Texas, aged 64 died suddenly, June 22, of heart disease

Harrie Milton Gardner, Cambridge, Mass. University of Vermont College of Medicine, Burlington 1895, member of the Massachusetts Medical Society aged 64, died May 11, of cirrhosis of the liver

William Fletcher Penn, Tuskegee Ala., Yale University School of Medicine, New Haven Conn. 1897 connected with the Veterans Administration Facility aged 62, died, May 31, of chronic myocarditis

Elbert L. Huestis, Colorado Springs, Colo. Medical College of Ohio Cincinnati 1888, aged 71 died May 8, in the Modern Woodmen of America Sanatorium, Woodmen, of pulmonary tuberculosis

Charles G. Parker, Gallipolis Ohio Medical College of Ohio Cincinnati 1888 member of the Ohio State Medical Association for many years coroner aged 76, died June 12 of heart disease

Samuel Johnson Stewart, Seattle Hahnemann Hospital College of San Francisco 1897, Medico-Chirurgical College of Philadelphia, 1901, aged 71 died May 14 of arteriosclerosis and heart disease

Herbert Harmon Purinton, Somersworth N. H. Medical School of Maine Portland 1891 member of the Massachusetts Medical Society aged 69 died June 7, of diabetes mellitus

William W. Pirkle, Cumming Ga. Atlanta Medical College, 1897 member of the Medical Association of Georgia,

formerly mayor, aged 64, died suddenly, June 8, of heart disease

John P. Neely, New London, Mo., College of Physicians and Surgeons, Keokuk, Iowa, 1877, formerly county coroner, aged 80, died, March 31, at Palmira, of cerebral embolism

Raymond Hayes Spence, Painesville, Ohio, Miami Medical College, Cincinnati, 1901, aged 58, died, May 28, in the Lake County Memorial Hospital, of coronary occlusion

Clarence James Whalen, Utica, N. Y., Syracuse University College of Medicine, 1904, on the staff of the Faxon Hospital, aged 52, died, May 21, of lobar pneumonia

Alexander Patterson, Oakland, Calif., Cooper Medical College San Francisco, 1893, served during the World War, aged 70, died, May 29, of arthritis and pneumonia

Edward Frank Partello, Detroit, Dutton Medical College, Chicago, 1899, veteran of the Spanish-American War, aged 69, died, June 17, of cardiovascular renal disease

Joseph H. Hindman, Humboldt, Kan., Kansas Medical College, Medical Department of Washburn College, Topeka, 1895, aged 61, died, May 27, of spinal sclerosis

Alvah Negus, Keswick, Iowa, State University of Iowa College of Medicine, Iowa City, 1906, served during the World War, aged 68, died, April 15, of encephalitis

Joseph Montgomery Slaughter, Van Alstyne, Texas, Tulane University of Louisiana Medical Department, New Orleans, 1904, aged 53, died May 10

Charles Chandler Farmer, Centralia, Mo., University of Missouri School of Medicine Columbia, 1898, aged 61, died, May 25 of acute edema of the lungs

Bernard M. Ross, Holland Mich., Eclectic Medical Institute, Cincinnati, 1882, aged 74, died, May 21, of pulmonary edema and multiple spinal sclerosis

John Edgar Walsh, Washington, D. C., Columbian University Medical Department Washington, 1890, aged 69, died, June 22, of cerebral hemorrhage

Jacob Mendelsohn, New York Columbia University College of Physicians and Surgeons, New York 1922, aged 33, died, May 8, of tuberculosis

Aaron W. Snyder, Indianapolis, Central College of Physicians and Surgeons, Indianapolis, 1901, aged 81, died, June 13, of cystitis and chronic prostatitis

James Lupton Neave, Zanesville, Ohio Miami Medical College Cincinnati 1874, aged 84, died, June 17, in the Good Samaritan Hospital, of senility

Elihu Duane Tallman, Covert, Mich. University of Michigan Medical School, Ann Arbor, 1882, aged 79, died, June 6, of chronic myocarditis

Charles Cecil Huff, Homestead, Pa., University of Michigan Homeopathic Medical School, Ann Arbor, 1881, aged 79, died June 12, of heart block

William Brownlow Spoon, Morristown, Tenn., Chattanooga Medical College, 1893, aged 69, was killed, May 27, in an automobile accident

John Phillip Ott, Columbia, S. C., Medical College of the State of South Carolina Charleston, 1878, aged 79, died, April 29, of heart disease

Benjamin Baumoebl, New York, University and Bellevue Hospital Medical College, New York, 1913, aged 44, died, May 18, of myocarditis

Carmen Frank Russo, Chicago University of Illinois College of Medicine, Chicago, 1931, aged 32, died, May 25 of pulmonary tuberculosis

Henrietta A. Buchanan, Cincinnati Woman's Medical College of Cincinnati, 1894, aged 79, died June 11, of chronic interstitial nephritis

Dodson Ramseur Schenck, Greenville, S. C., Jefferson Medical College of Philadelphia, 1883, aged 73, died, June 7, of angina pectoris

Norman M. Spradley, Boonville, Ind. Louisville (Ky.) Medical College, 1890, aged 73, died, June 4, of cerebral arteriosclerosis

John H. Stigall, Burnside Ky. University of Louisville School of Medicine, 1889, aged 72 died May 28, of cerebral hemorrhage

Harry E. Palmer, Dayton, Ohio New York Homeopathic Medical College, 1885, aged 76, died, May 20, of cerebral hemorrhage

William C. Reid, Oakland, Calif., University of Louisville (Ky.) School of Medicine, 1877, aged 80, died, May 6, of pneumonia

## Correspondence

### ESTIMATION OF VITAMIN C

To the Editor—I enjoyed reading the editorial on the estimation of vitamin C in *THE JOURNAL*, June 2. May I call your attention to one sentence in the first paragraph, which states that vitamin C is clearly recognized as one of the hexuronic acids. This is, I believe, an error of chemical description.

R. B., New York

NOTE—Our correspondent is quite correct in pointing out that ascorbic acid, now identified with vitamin C, can no longer be regarded as one of the hexuronic acids, since its structure has been clearly demonstrated. E. H. Farmer (Annual Reports on the Progress of Chemistry for 1933, p. 167) says: "Szent-Gyorgyi's compound is not a member of the uronic acid class and has been renamed ascorbic acid." This statement is evidently based on an article by Haworth and Szent-Gyorgyi (*Nature* 131:24, 1933) in which it appears that

in view of the fact that (1) hexuronic acid is the name of a class of substances rather than that of one individual compound and that (2) the material described as a hexuronic acid isolated from adrenal cortex and now from Paprika contains a molecule of water less than is required for a hexuronic acid, we wish to ascribe the name ascorbic acid to the crystalline substance  $C_6H_8O_6$  which has been the subject of earlier communications from our laboratories.

The uronic acids, of which glycuronic acid is a typical example, have the empirical formula  $C_6H_{10}O_7$ . They contain both an aldehyde and a carboxyl group. The formula for ascorbic acid is

(Compare Hirst and others, *J. Chem. Soc.*, 1933, pp. 1270, 1419, 1564, 1934, p. 62)—ED

### TINTED LENSES IN OPHTHALMOLOGY

To the Editor—I congratulate W. W. Coblentz for calling attention to the unproved theories and extravagant claims made by certain manufacturers concerning tinted lenses. In his effort to emphasize his criticism, however, I feel that he has gone too far in creating the impression that tinted lenses are without merit. Tinted lenses have a definite and positive therapeutic value in many ocular diseases. I base this statement not on theory but on practical experience in prescribing tinted lenses for many purposes over a period of many years and on the answers to a questionnaire recently addressed to prominent ophthalmologists throughout the United States. The replies are all from ophthalmologists certified by the American Board of Ophthalmic Examinations and from eye surgeons in various sections of the country, representing a cross section of the ophthalmic profession. A great majority of these recommend the use of tinted lenses for the following diseases of the eye: acute, subacute and chronic conjunctivitis, chronic blepharitis, blepharospasm, vernal conjunctivitis, trachoma, phlyctenular conjunctivitis, keratoconjunctivitis, interstitial keratitis, iritis, iridocyclitis, incipient cataract, postoperative cataract, uveitis, scleritis, neuroretinitis, retinitis, retinitis pigmentosa, retinal hyperesthesia, optic neuritis, myopia, aniridia, photophobia, albinism, and blond approaching albinism.

There is added to this long list of diseases the following persons who are generally nervous (sympatheticotonia): those engaged in occupations requiring exposure to sunlight or constant, bright, artificial light; automobile driving; exposure to sunlight, reflection from sand, water and highways. To these I add my own suggestion—persons wearing moderate and high grade myopic lenses.

My chief complaint is based on Coblentz's evaluation of tinted lenses purely on their physical properties resulting from 'test tube' experiments, that he has failed to give consideration

to the many disease conditions of the eye, and that he has regarded the human eye as a camera and has failed to realize that vision is concerned not only with the eyeball itself but with the central nervous system, particularly a sympathetic nervous system and a series of visual centers and subcenters in the brain, all of which react directly or indirectly under the influence of light.

Judging that Coblentz has based his remarks in *THE JOURNAL* of April 14 on another article published in the *American Journal of Ophthalmology* in October 1932, I take it that his analysis of the value of tinted lenses is based on their transmission properties. From a laboratory standpoint his assumption is true, but only in the use of tinted glasses for industrial purposes to protect the eye from ultraviolet rays used in industries and from infra-red rays in occupations under great heat. He has arrived at the conclusion without proof that a tinted lens in order to eliminate glare must be so dark that it would reduce considerably visual acuity and would be impossible for use at night.

I wish to correct this error. There is a definite physiologic and pathologic disturbance of the retina known as hyperesthesia. It is just as distinct an entity as allergy of the skin in persons in whom dermatographia may be produced by mechanical irritation. Just as some persons are sensitive to heat and mechanical irritations, so the eyes of certain individuals are sensitive to light. Nearly every individual has a certain tolerance to the glare of light. This degree of tolerance varies very widely in persons of dark complexion compared with blond.

Most often pigmentation of the retinal epithelium of the eye determines the tolerance to light. For hyperesthetic individuals it is only necessary to reduce the glare in a sufficient degree to bring about tolerance to light in that particular person. Therefore it is entirely erroneous for the physicist to tell the ophthalmologist that in order to reduce glare in a given individual it is necessary to eliminate light itself. There is no intent on the part of tinted lenses to eliminate glare completely but to reduce it in such a manner as to make it tolerant. Therefore I have found in my own practice that the light tinted lenses are of great importance for constant wear in those individuals who have an unusual sensitivity to glare or to light itself.

Coblentz fails to recognize certain pathologic states of the eye that require tinted lenses in order to bring about comfort for the patient. He has failed to realize that many children with photophobia due to a supersensitive nervous system may have endocrine disturbances or infections, as in the case of chorea. These cases are greatly benefited by light tinted lenses aiming to cut down only partially the sensitivity of the retina, which in turn reduces the sensitivity of the general nervous system.

The whole matter of tinted lenses in ophthalmology needs investigation. For over a year I have been collecting data on this particular subject and am now making a detailed study which may lead to a clearer understanding from the ophthalmologist's point of view as to the need of tinted lenses in various pathologic states and in the apparently normal eye with marked reduction of pigment in the uveal tract. It is hoped that with the completion of this study there will be a more rational understanding of the indications for colored glasses.

If the manufacturers of tinted lenses have exaggerated their claims, and I believe some have, it is because the physicists, the ophthalmologists and the makers have not joined forces in determining the exact status of this type of lenses. Many thousands of people wear tinted lenses with comfort not obtainable with nontinted lenses. Many physicians wear them and defend their value. If the public has discovered the value of colored lenses for which the physicist and ophthalmologist have not yet found an explanation then the scientist is at fault.

Cod liver oil was used for many years before it was found that vitamin A and D were the basis for its value. I am sure that the reason will soon be discovered for the use of tinted lenses for everyday use for individuals who wear them with comfort.

LOUIS LEHRFELD, M D, Philadelphia

NOTE—This letter was referred directly to Dr W W Coblentz, who replies

To the Editor—The function of the Council on Physical Therapy is to keep the medical profession and the public informed regarding developments in apparatus and devices having a direct application in medicine.

At the annual meeting of the Council last December I was requested to survey the advertising situation of tinted lenses. The manuscript report was read by a physicist qualified in physical optics, selected by myself, and an ophthalmologist of recognized standing selected by the Council. Both readers approved of the presentation and both thought I was too generous in my discussion and too optimistic in my conclusions regarding the advertising situation. With the approval of the Council as a whole the paper was published in *THE JOURNAL*, April 14. As was to be expected, the article has brought forth comments both favorable and unfavorable, the latter apparently based to some extent on a misconception of the aims and purposes of the survey.

While Dr Lehrfeld's discussion is ultracritical and in places is open to question (e g, dark glasses for night driving) as a whole it is constructive and is a step in the right direction. As pointed out in my earlier discussion of the subject (*Am J Ophth* 15 932 [Oct] 1932) it is the duty of researchers in ophthalmology to prescribe what is needed, instead of allowing themselves to be told by advertisers of new fangled lenses of improved merits.

A few comments on Dr Lehrfeld's paper are in order. At the outset it is to be distinctly emphasized that neither the Council as a whole, nor myself, who have become personally responsible because my name is attached to the paper, desire to give the impression that "tinted lenses are without merit."

My discussion of the tinted lens situation is confined to the advertising situation, not to the prescribing of tinted lenses to alleviate disease conditions of the eye. In accepting physical therapy devices the Council makes the broad distinction that the advertiser shall confine himself to descriptions of the construction and operation of his device, leaving diagnosis and treatment to the medical profession. If the paper apparently has failed to give due consideration to the many disease conditions of the eye it is because the reader has misunderstood the scope of the survey.

Dr Lehrfeld's enumeration of the various diseases of the eye for which tinted lenses are recommended should prove useful in future considerations relative to the use of tinted lenses for healthy and diseased eyes. But as he so aptly points out, since, for hyperesthetic individuals the shade of lens to be prescribed to bring about tolerance of light varies with the particular person it seems hazardous, at least until the subject is better understood, to use the physiologic test instead of the physical evaluation of the lens by the "test tube" method, which Dr Lehrfeld criticizes.

For the present it seems to me that the surest procedure to guard against the effects of glare is to determine the transmissive property of the tinted lens. For example, just now I am making measurements of solar ultraviolet radiation in Arizona, at altitudes of 7,000 and 11,000 feet, under an illumination of some 10,000 foot candles. The tinted lens commonly worn is a shade 3, opaque to ultraviolet and infra-red, transmitting about 14 per cent of light, visible radiation. Tem-

porarily I attempted to use another similar type of lens, apparently only slightly lighter in color. Finding that it was producing eyestrain and headache, I shipped it to the National Bureau of Standards, receiving a report that it transmitted 29 per cent visible radiation. Evidently the eyestrain was caused by the excess light transmitted.

Dr Lehrfeld's statement that "the whole matter of tinted lenses in ophthalmology needs investigation" is entirely in agreement with what I have claimed all along. My own contribution has been and will continue to be the description of the physical (transmissive) properties of tinted lenses, looking forward to the correlation, if any, of the physical properties with the physiologic observations. In the meantime Dr Lehrfeld's promised contribution to the ophthalmologic questions will be awaited with interest.

W W COBLENTZ, PH D,  
Lowell Observatory,  
Flagstaff, Ariz

### SIMULTANEOUS IMMUNIZATIONS

To the Editor—I am interested in the communications on simultaneous immunizations in *THE JOURNAL*, April 14, April 21 and June 2.

I was in charge of a mobile clinic in Utah from June 1928 to April 1930 for the prevention of disease. During one year I gave more than 63,000 doses of vaccine. Experience proved that a person could be immunized against diphtheria, typhoid and smallpox at the same time without more reaction than one gets from vaccine given for only one disease, as nearly as I could judge.

From April 1930 to September 1930 I served as director of the Utah County Health Unit at Provo, Utah. From September 1930 to July 1933 I served as director of Gila County Health Unit at Globe, Arizona. As deaths were occurring in Gila County from both typhoid and diphtheria and as smallpox was present I gave simultaneous inoculations for all three diseases to thousands of persons. Several schools were inoculated 100 per cent. About 10 per cent of those inoculated complained of reactions, about 1 or 2 per cent were quite ill for a day or so.

Some French observers state that a much higher percentage are made Schick negative by giving typhoid vaccine with the diphtheria toxoid.

My successor as director of the Gila County Health Unit at Globe reports that he Schick tested 350 pupils in one group and 180 in another that I had inoculated two years previously. One in seventy were Schick positive in the larger group and one in sixty in the smaller—over 98 per cent protected.

In order to avoid severe reactions in giving typhoid vaccine I believe that the dose should be carefully proportioned to the weight of the child, 0.5 cc used for the first dose and 1 cc for the second and third doses being taken as the standard for a 160 pound (72 Kg) man. The dose for a woman weighing 160 pounds should be about 20 per cent less, and any person having a sharp reaction should be given a smaller dose next time.

It was also a fact that parents would bring children for three inoculations but if one wanted them to come oftener they frequently would not do so. The children usually developed a fixed dislike to getting inoculated after three doses. If vaccines are not given simultaneously, the children usually are not protected from more than one disease.

During five years of active experience there were no fatalities, no one was made seriously ill, and no lasting ill effects were observed. But in that part of the country there are a lot of graves of persons who died of preventable diseases unprotected.

A C MCKEAN, M D, Norway, Iowa

## Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

### ESSENTIAL HYPERTENSION IN A YOUNG GIRL

To the Editor—Miss R. H. aged 17 came under my observation in July 1933 giving a history of high blood pressure, frequent headaches and excessive sweating. Physical examination was negative except for flushing of the face, transient erythematous mottling of the neck, slight fullness of the thyroid and a heart rate of 120. The weight was 100 pounds (45 Kg). Urinalysis gave negative results. The basal metabolic rate on various occasions was  $-4$   $-7$   $+4$   $+4$   $-11$   $-2$   $+8$   $+3$ . A chest roentgenogram showed the lungs normal and the heart normal in size and shape. An electrocardiogram was entirely normal once and showed a flattened T wave in the second lead in a later tracing. The blood Wassermann reaction was negative, the blood nonprotein nitrogen was 31 and sugar 103. Fundus examination showed slight tortuosity of the vessels. Further roentgen studies showed a suggestion of calcification of the vessels of the forearm. The cranial vault showed evidence of increased convolitional markings, the sella turcica was small and flattened, the floor well preserved. The systolic and diastolic blood pressure fluctuates between 150/102 and 174/124. The latter blood pressure reading was taken this month, the patient feeling fine and showing a gain of 7 pounds (3.2 Kg) over her first recorded weight. Medication with thyroid extract and phenobarbital in small doses has had no effect on symptoms or blood pressure. Is essential hypertension the only diagnosis possible? What is the probable prognosis? Please omit name.

M D New York

ANSWER—Essential hypertension is not the only diagnosis possible. In fact, essential hypertension is never a complete diagnosis, for all instances of hypertensive disease must have some etiology. When the etiology cannot be found, it is perhaps wiser to call the disturbance "hypertensive disease, etiology undetermined." This is an unusual instance of marked arterial hypertension, since it occurs in a girl so young and apparently free of objective evidence of a source or sources of intoxication.

The patient presents conspicuous evidence of marked vasomotor instability, as shown by the intense flushing and mottling of the skin, tachycardia, cephalalgia and hyperhidrosis. In part the arteriolar hypertonia may be of emotional origin, psychologic probing into the emotional life of the patient may possibly reveal intense and continuous violent conflicts. Characteristic of this form of hypertonia is the acute and violent rise in arterial tension that occurs when there is proper emotional stimulation, often a rise of from 50 to 70 mm of mercury in a few seconds is noted. These acute exacerbations are frequently accompanied by the vasomotor phenomena described. However, in the great majority of patients with purely emotional hypertension the arterial tension falls to or near normal levels when emotional calm is induced, unless the process has continued so long that progressive arterial hypertensive disease is well established.

The possibility of coarctation of the aorta must be constantly borne in mind in differentiating the etiology of hypertension in one so young as this patient. Although this congenital anomaly accounts for perhaps but one of every thousand cases of hypertension, it must not be forgotten. It may be readily ruled out by determining the arterial tension in the lower extremities, with no stenosis of the aorta this is invariably somewhat higher than in the arms, whereas in the presence of coarctation the tension in the legs is much lower.

Hyperepinephrinemia, due to suprarenal chromaffin cell neoplasms, has been found to be the explanation of a few isolated instances of severe and almost uncontrollable arterial hypertension in young persons. This rare form of hypertension of hormonal origin should show conspicuous evidences of vasomotor hyperirritability, as does the present patient. These patients frequently show disturbed dextrose metabolism and a lowered tolerance to administered dextrose. Dextrose tolerance studies on this patient are indicated.

The relation of pituitary disorders to hypertensive disease is not clearly understood as yet. That the pituitary gland secretes a hormonal pressor substance is unquestioned, but whether or not perversion of secretion or hypersecretion of this substance is clinically a frequent or significant etiologic factor in hypertension is unsettled. The data presented in the query indicate no gross evidence of pituitary change, either in the roentgenologic examination of the sella turcica or in the weight and physique of the patient. Nothing was stated about any menstrual irregularities.

The significance of the suggested calcification in the vessels of the forearm is difficult to evaluate. It has been suggested

that hypertension may be due to a hypocalcemia such as occurs in parathyropriopia. The evidence in favor of this conception is far from convincing and other studies indicate that any relationship between the blood calcium content and the arterial tension are of physiologic rather than pathologic import. At present presenile calcium deposition in the sternal cartilage is being found more and more frequently by roentgenologists in young persons. Whether this increased frequency and degree of unusual calcium deposition has any association with the far more general and liberal use of vitamin D concentrates is, of course, most uncertain, but it is a stimulating thought. Calcification in the larger arteries is by no means a common phenomenon in hypertensive disease, even in much older patients, and frequently occurs quite independently of any elevation of the blood pressure. Hypertensive disease is a hypertonic disturbance of the arteriolar media, whereas arteriosclerosis is an entirely separate entity involving the intima of the larger vessels.

If the true underlying etiology of this girl's hypertension is not found and eradicated, or at least ameliorated, the prognosis is poor. The patient is in no immediate jeopardy, but if the hypertension should continue for any great length of time the progressive degenerative changes of arterial hypertensive disease are inevitable. The ophthalmoscopic evidence of increased tortuosity of the retinal vessels indicates that some of these changes have already occurred. These are the result and not the cause of the disease. It may be taken as a general clinical axiom that the earlier in life hypertensive disease starts the more rapid are the progressive degenerative changes and therefore, the worse the prognosis. Naturally there are exceptions to this general rule, but it is applicable in the great majority of cases.

### TOXIC EFFECTS OF BEE STINGS

To the Editor—A man aged 38 has a peculiar reaction following a sting by bees, wasps, humbehecs or hornets. In about two minutes a severe palpitation develops with an increase in the pulse rate to 120 per minute or higher. A 'roaring and pounding' develops in his head. On one or two occasions he has lost consciousness although this is not the rule. Urticarial eruptions soon appear. These are chiefly in the nature of puffing of the lips and face, eruptions on the extremities and occasionally the swelling of an entire extremity, usually not the one on which the sting occurred. There is usually no wheal at the sight of the sting but an oozing of a few drops of blood. Within about three quarters of an hour the symptoms gradually begin to subside and at this time a more or less generalized pruritus begins. The man formerly kept bees and was stung often without these reactions. He left his business of farming to serve in the World War. Since returning to his farm he has the reactions every time he is stung, possibly a dozen or more different times. Would the reaction be classed as an anaphylaxis? If so, is there some way in which the man may be desensitized? What should be done in the line of prevention of these reactions and treatment in case of their occurrence? Your opinion will be appreciated. If this is published kindly omit name and address.

M D Wisconsin

ANSWER—The literature contains a number of references dealing with the marked toxic effects of the sting of bees. In discussing the general question it is important to realize that any of three possible reactions may take place. The first is the toxic effect of the venom contained in the stinger. This material is toxic to man and affects every one if the dose is adequate. Some individuals may respond to a very small dose. The symptoms described consist mainly of circulatory collapse, coma and hemolytic changes in the blood stream. It is not to be regarded as an anaphylactic or allergic reaction.

Another type of reaction as the result of the sting of bees is allergic. This may consist of any of the symptoms commonly seen in ordinary clinical manifestations of allergy. Generalized urticaria and angioneurotic edema have been most frequently described. Asthma or hay fever has also been described as an effect of bee sting. Two possible explanations for the allergic reaction have been advanced. One is that the individual is pollen sensitive and the bee sting has introduced pollen (Gibb, D. F. Anaphylaxis from Pollen Introduced by Bee Sting, *Canad M A J* 19 461 [Oct.] 1928). From the more recent observations by Benson and others it seems unlikely that this is an important cause of allergic reaction.

The most exhaustive piece of work on allergy from bee sting (Benson, R. L., and Semenov, H. Allergy in Its Relation to Bee Sting, *J Allergy* 1 105 [Jan.] 1930) appears to indicate that the symptoms produced are due neither to the toxic fraction of the poison nor to the pollen but rather to the protein of the bee. These authors found that, after removal of the poison from the stinger mechanism, extracts of the stinger and of the body of the bee were capable of producing allergic responses in a sensitive individual.

Attempts at desensitization are worthy of trial (Braun, L. I. Desensitization of a Patient Hypersensitive to Bee Sting, *South*

*African M Record* 23 408 [Sept 26] 1925, and also Benson and Semenov) The last mentioned authors extracted the venom free stingers and the body of the bee separately and gave injections with gradually increasing doses with an apparently almost complete clinical desensitization For details the reader is advised to consult Benson's original article For prevention of reactions other than specific desensitization it is possible that the administration of ephedrine about one-half hour preceding exposure might be of partial benefit For the treatment of the reactions, epinephrine hypodermically should be the most efficacious remedy For more prolonged effect after epinephrine has been administered, ephedrine orally should be used

#### SENSITIZATION TO BLOOD—SENSITIVITY TO GASOLINE

*To the Editor*—1 Can a state of sensitivity or anaphylaxis to human blood (serum or whole) be induced in a human being by the intramuscular subcutaneous, intraperitoneal or intravenous injection of human blood? For example, if in infancy or later it is necessary to inject whole blood or convalescent serum for some reason will the patient become sensitive to human protein (blood) so as to make it dangerous to give him a blood transfusion or other injection of blood at some subsequent time? 2 Is there any way to desensitize a patient who is sensitive to gasoline? He is a mechanic and his being sensitive to this fuel makes his work in a garage irregular because of the severe skin reaction he suffers when he gets it on his clothing or body A patch test with one drop produced an intense reaction in about two hours with the development of a bulla locally and some general itching Please omit name state and address

M D Ohio

*ANSWER*—1 Although the possibility of sensitization to the proteins of the human body or its secretions has been suggested, the major opinion is that such an occurrence is not likely The reports of such occurrences are not well authenticated An individual may become sensitized, however, to a specific substance (horse dander, for example) by being transfused with the blood of an allergic person sensitive to that substance

2 Contact dermatitis due to occupational irritants is extremely difficult to manage Two possible methods of therapy may be considered The gasoline could be diluted with an oil such as almond oil and, beginning with small doses by subcutaneous or intramuscular injection, one may succeed in finally arriving at a dose which will protect the patient The other alternative is to have the patient bathe himself daily with water containing increasing amounts of the gasoline With both methods great care must be exercised because of the possibility of producing a widespread reaction It must be emphasized that such methods of therapy are as yet in the experimental stage

#### ULCER OF DUODENUM IN A CHILD

*To the Editor*—A girl aged 6 years vomited bile and had a temperature of 101 F at 1 p m October 7 The area over the appendix and especially from the appendix to the costal margin was tender The child had had several previous attacks and a druggist had given her mild mercurous chloride in small doses The child lived in Detroit and had come here October 7 with her mother At 7 p m she was in shock and died at Mercy Hospital The intern performed a post mortem which revealed a severe peritonitis beginning at the pylorus and extending about 12 inches There was also a severe parietal peritonitis After the inflamed covering was stripped from the duodenum the bowel for 12 inches looked as though it had been boiled When it was opened it had a fiery red and thickened appearance I can find only slight information in my books on duodenitis Is this condition rare or is it more than just a duodenitis? My fellow physicians are also puzzled Please omit name

M D Ohio

*ANSWER*—The clinical and pathologic observations in the case of this child, suffering with fever, vomiting and abdominal tenderness are not as detailed as one might wish to aid in an adequate explanation for the condition that caused her death

The localized peritonitis involving 12 inches of the duodenum would lead one to wonder as to the condition of surrounding organs, such as the pancreas the bile duct, the ampulla of Vater and the arteries and veins supplying the duodenum

The boiled appearance of the duodenum with the fiery red thickened appearance of its interior, together with the localized peritonitis, gives the impression of some sort of duodenal ulcer The most frequent type of ulcer of the duodenum which occurs in childhood is that found in new born and very young infants In the new born period such ulcers may be manifested clinically by hematemesis or melena In later infancy, those who have suffered from wasting illness are prone to develop such ulcers These may cause erosion of blood vessels and thereby hemorrhage, or a complete destruction of the intestinal wall may result in perforation

Following burns or scalds, an acute ulceration of the duodenum, known as "Curling's ulcer," may result It is believed that these ulcers are found in cases in which sepsis is associated with the burn, giving rise to septic emboli capable of producing hemorrhagic infiltration in the alimentary canal

Tuberculous ulceration of the duodenum is much less frequent than such ulcers occurring in the lower ileum

The perforation of acute duodenal ulcers, such as those following burn, septic processes and typhoid, are rarely recognized at the bedside Acute perforation of a chronic ulcer is characterized by sudden onset with pain, vomiting and collapse In the history of the case in question there had been several previous attacks, presumably of abdominal pain and vomiting

A subacute perforation of a duodenal ulcer may begin with sudden pain, followed by vomiting and prostration The opening may have been small, and a thick mass of adherent lymph may cover the duodenum at this point

While the finding of an ulcer or perforation is not mentioned in the pathologic examination of this case, the existence of a subacute perforation would explain the localized peritonitis, the external appearance of the bowel and the internal inflammation The occurrence of such a condition in a 6 year old child would be unusual and rare Perforation by a sharp foreign body that had passed through the intestine might be a possible cause

Thrombosis of the branch of the pancreatoduodenal artery supplying the involved portion of the duodenum might result in such a clinical and pathologic picture

The condition termed duodenitis is a catarrhal inflammation of the duodenum, probably associated with a catarrhal gastritis or cholecystitis The symptoms produced by such a condition in the duodenum would be altogether different from those described in the case here considered

#### TRICHLORETHYLENE AND ASTHMA

*To the Editor*—Does the vapor of trichlorethylene aggravate asthma? This question is asked by an asthmatic patient who has been working during the past three years in a dry cleansing plant where for the past two years trichlorethylene has been used and he comes in contact with the vapor two or three times a day for a few minutes Sometimes the effect is such as to make him feel drunk and requires his going out of the plant into the fresh air During the past two years his asthma has been worse than it was the year prior to these exposures to trichlorethylene There is no legal action involved in this case Please omit name

M D Massachusetts

*ANSWER*—The vapor of trichlorethylene, like vapors of all other noxious materials, does aggravate bronchial asthma However, it is not the cause of the attacks, as no cases have ever been reported due to this agent It merely acts like the fumes of coal gas, sulphur and other chemicals by making the asthma worse than it would otherwise be

It would seem in this case that the exposure to the vapor is too slight to be of much importance The fact that the asthma is worse has probably no relationship to the exposure to the chemical

This patient, like all other asthmatic patients, should be thoroughly studied from the allergic standpoint, this should include a careful history, an examination, Wassermann test, urine blood and sputum tests and a roentgenogram of the chest In addition, complete protein sensitization tests should be carried out

#### SENSITIVITY TO SUNLIGHT

*To the Editor*—Please give me references or suggest a line of treatment for a patient who is hypersensitive to direct sunlight and to ultra violet rays Even short exposure produces the next day an erythematous rash with pruritus which is not easily controlled by ordinary local applications Apparently no increased resistance is developed by one attack for the reaction to each subsequent exposure is of equal severity Please omit name

M D Wyoming

*ANSWER*—There are two types of sensitiveness to sunlight The first reacts at the point of contact soon after exposure to light with an edematous reaction confined to the point of contact with light, i e, by a typical hive reaction This reaction may be delayed one or several hours, but rarely for twenty-four hours

The second type of case reacts at the point of contact with light with eczema, characterized by itching redness of the skin secretion and scaling This reaction is always delayed and instead of disappearing promptly as the hive case, becomes more pronounced on the second day and usually persists for one week

Both types of case can be treated with ultraviolet rays in doses preferably just short of the amount that produces a local

reaction The rays should be applied generally, points of natural exposure, such as the face, neck and hands, being avoided The hive cases, on account of the quickness of appearance and disappearance of the reaction, can be treated at intervals of from one to three days However, the eczematous type should not be treated so often In both types, exposure of the skin to undue amounts of sunlight should be avoided by having the patient stay indoors on bright days, or protect the skin with colored scarfs on venturing out doors Overexposure of a gross amount of skin to excessive doses of radiation may result seriously, so that treatment should be given with great care The reader is referred to "Treatment of Physical Allergy" (treatment of heat and effort sensitiveness and cold sensitiveness and treatment of contact urticaria caused by light, cold and scratches) by W. W. Duke, *J. Allergy* 3:408 (May) 1932

#### TREATMENT OF SYPHILIS

*To the Editor*—A man aged 28 came to me saying that he contracted syphilis while in college and received prompt and rather extensive treatment He states that he had in all about forty injections of neoarsphenamine and a smaller number of injections of bismuth and mercury compounds and bismuth arsphenamine sulphate The Wassermann reactions became negative after the third series of injections and has remained so Each year he has had his blood examined and it was for this he came The report on the specimen I drew was 4 plus He desires treatment The literature of syphilis with its conflicting claims for the various soluble and insoluble preparations of bismuth and mercury and the numerous arsenicals makes one wonder whether there is any consensus among syphilologists as to the proper regimen in a given case I would value your opinion on this case I should add that physical examination is negative No spinal tap has as yet been made Please omit name

M. D. Oklahoma

*ANSWER*—The Wassermann test in this case should be repeated and, if still found to be 4 plus, treatment should be commenced If the spinal fluid and physical examinations are negative, the case can be classified as asymptomatic or latent There is no consensus among syphilologists as to the proper regimen in any stage of syphilis The general trend is toward a combined therapy with one of the arsenicals conjointly with the heavy metals bismuth or mercury compounds, and iodides in the interim Some men feel that arsphenamine gives better results than neoarsphenamine Others prefer bismuth arsphenamine sulphate or silver arsphenamine The large number of bismuth preparations put out by different manufacturers adds greatly to the confusion The brands accepted by the Council on Pharmacy and Chemistry may be given the preference The number of courses to be given, the total dosage and the duration of the treatment will depend on the response of the patient and periodic serologic control Valuable information as to the treatment of syphilis may be found in the recent books by Schamberg and Wright and by Moore

#### ALUM PRECIPITATED DIPHTHERIA TOXOID

*To the Editor*—Will you please give me information about toxoid and alum precipitate? Would you advise giving it as a public health immunization from the age of 6 months through 8 years? Is the technique of giving it any different than when using the toxin antitoxin?

INQUIRER

*ANSWER*—Alum precipitated diphtheria toxoid, "alum toxoid" for short, is a grayish white precipitate suspended in physiologic solution of sodium chloride Diphtheria toxoid is adsorbed by this precipitate The antigenic value of the alum toxoid is determined by its power to induce the formation of diphtheria antitoxin on injection into a guinea-pig The indication for the use of alum toxoid is susceptibility to diphtheria

For practical purposes all children of preschool age are regarded as susceptible, and the preferable age for preventive immunization by means of alum toxoid is between 6 months and 2 years In children over 8 years of age the question of susceptibility should be determined by means of the Schick test The alum toxoid may be obtainable in packages containing one or more immunizing doses Active immunization is effected by injecting a single dose of alum toxoid subcutaneously at the insertion of the deltoid muscle or in younger children between the shoulder blades Before injection the vial containing the alum toxoid must be shaken vigorously because, as stated, it is the precipitate that carries the immunizing toxoid There may remain for weeks a swelling or lump at the site of injection, because the material is absorbed slowly Immunity develops gradually, as a rule the Schick test becomes negative six weeks or so after the injection Up to this time at least, one dose of alum toxoid has given highly satisfactory results and the method appears to be an advance of great practical value

#### HEAT TREATMENT OF MULTIPLE SCLEROSIS

*To the Editor*—In the April issue of the *Ladies Home Journal* appears a very pretentious article entitled Young Doctor Heat written by Paul de Kruijff This article has been read and thoroughly digested by an intelligent patient of mine aged 39 and a victim of multiple sclerosis Naturally he is willing to try anything to produce a cure Mr de Kruijff's article speaks of a mechanical fever booster which is now in use at the Mayo Clinic the Cleveland City Hospital the Milwaukee General Hospital and the Henry Ford Hospital in Detroit The article mentions multiple sclerosis among the hopeless diseases that are being benefited Apparently the latest, finest "hot box" is the new Vapotherm built by George H. Spencer Can you tell me whether any patient would be justified in undertaking the trouble and expense of a course of treatment with this artificial temperature producing machine? The blood and spinal fluid Wassermann reactions are negative Please omit name

M. D., New York

*ANSWER*—There is probably no disease in which it is more difficult to gauge the effects of therapeutic efforts than multiple sclerosis The course of the disease is extremely chronic, and remissions and exacerbations are frequent even without treatment Consequently, new methods are liable to meet with undue optimism when improvements arise from natural causes rather than from the method applied Fever therapy in this disease is not founded on a rational basis but has been applied empirically, mainly with the realization that nothing else has produced results While claims have been made that improvement has followed this procedure, facts available are not sufficient to justify much hope of success The causative factor of multiple sclerosis is as yet unknown While it has been alleged that a spirochete has been observed, this has not been proved and the pathologic changes are not in any way similar to those produced by the spirochete of syphilis or other invading organisms The disease attacks primarily the myelin sheaths, causing their dissolution The scar, or patch of sclerosis, is the terminal stage of this process and is permanent when once formed, though the loss of the myelin sheath does not necessarily mean the death of the nerve fiber There is some evidence to suggest that this process of demyelination results from the action of a ferment of some kind It has been demonstrated also that some such ferments are inhibited or neutralized by quinine On this basis Dr. Richard M. Brickner of New York has employed quinine in the treatment of patients with this disease and has reported facts which at least justify its continued application This procedure has at least some rational foundation and is without danger other than those that belong to an idiosyncrasy to quinine

#### EFFECTS OF SODIUM FLUORIDE

*To the Editor*—What effect if any would a 15 per cent aqueous fluoride solution used as a moth proofing agent on clothing rugs and furniture have on the human body? Would it cause a dermatitis? Kindly omit name

M. D. Connecticut

*ANSWER*—Glass etchers and embossers who use hydrofluoric acid are affected with slow healing burns and loss of the nails The double fluoride of sodium and ammonium produces the same results Ulcerations may develop also from the acid fumes of hydrogen fluoride evolved in the manufacture of hydrofluoric acid Fluoride of antimony is also used as a fixative for some of the basic dyes to produce some of the brightest and fastest colors It is questionable whether a 15 per cent aqueous fluoride solution used as a moth proofing agent on clothing, rugs and furniture would cause a dermatitis The most certain way of finding out would be to make a patch test, applying to the skin a square inch of gauze saturated with the solution and covered with rubber dam for twenty-four hours and noting the reaction, if any

#### HAZARDS OF BAKELITE INDUSTRY

*To the Editor*—The workmen on a job are exposed to a certain amount of inhalation hazard of a fine dust from bakelite this dust consisting of a phenol formaldehyde compound mixed with wood flour Would your consulting service be able to advise me whether there would be expected to be any definite health hazard to workmen on this job and if the hazard is great enough to justify the wearing of respirators?

GEORGE S. GILPIN, M. D. Cleveland

*ANSWER*—The operation described has been carried out in a number of plants utilizing bakelite The chief hazard appears to reside in skin irritation Especially during the summer months a fair number of those exposed may present an occupational dermatitis chiefly of the hands, but occasionally of the face or neck This irritation may involve the eyes and the membranes of the respiratory tract The wood dust is relatively unimportant, although not entirely harmless Apparently these workers are subject to increased probability of pneumonia The wearing of respirators in connection with this work is

attended by some difficulty, as the mechanical action of the respirator face piece is favorable to the production of a facial dermatitis. Instead, it is preferable that installation be made of spot exhaust systems at the point of origin of dust in the molding operation.

#### REFLEX PAIN FROM PROSTATIC URETHRA

*To the Editor*—A man aged 50, has had for three years an almost continuous and at times quite severe burning sensation on the under side of the penis just back of the corona. There is a slight redness of the skin and nothing more. He has some prostatic enlargement and has bloody seminal emissions. Cystoscopy shows a very large verumontanum with some ulceration. The median part of the prostate bleeds easily when touched. Applications of silver nitrate to the verumontanum and prostate have helped this but the burning of the penis continues. Can you give me any information about this burning and what to do for it?

W L LAMBERT, MD Asheville N C

*ANSWER*—Unless there is something more than a slight redness at the site of the burning sensation, and nothing is found in the anterior urethra at that point, the symptom can easily be explained as a reflex from the prostatic urethra. Similar reflex symptoms are quite common from that cause. Direct applications to the verumontanum do not as a rule relieve these symptoms. Much better and more permanent results are obtained by the passage of a full size sound into the bladder at weekly intervals or the use of the straight dilator into the anterior urethra, with gradual dilation till the maximum is reached. At times, instillations of weak silver nitrate solutions (from 1:3,000 to 1:500) into both the anterior and the posterior urethra with the Bangs sound syringe will be found to be efficacious.

#### WATER SOFTENERS AND DERMATITIS

*To the Editor*—Have you any data on hand in regard water softening machines and skin diseases? I have installed in my home a Twin City water softener which operates by running the water over a mineral (I do not know what it is and the agents here cannot or will not tell me what it is). Every so often the flow of water through the machine is changed and the mineral washed with salt water. This is called reconditioning and restores the mineral to its pristine purity. Now for reasons which are unimportant I have used this water to drink, being advised that it is pure. I developed a skin rash, which is almost intolerably itchy and which has baffled several skin men. I am wondering whether the water might be the cause. I have discontinued drinking it but not enough time has elapsed to give me much result as yet. Please omit name.

MD Ohio

*ANSWER*—It is presumed that the chemical employed in this form of household water softening is potassium-sodium-aluminum silicate. It is believed that this chemical is or is akin to the well known trade substances, "zeolite" and "permutite." "Green sand" is a widely used term designating this filtering medium. Calcium and magnesium unite with this silicate replacing the sodium present and thus accomplishing the softening process. Through the passing of brine over the filtering bed, the bed is chemically rejuvenated.

It may be doubted whether any change in the water produced by this procedure is associated with the causation of skin disease. To an even greater extent may it be doubted that the ingestion of this water is associated as the producing factor with any skin disease.

On occasion, the use of sodium carbonate in water softening may lead to skin disease from direct contact but not from water ingestion. Waters containing arsenic have produced systemic arsenic poisoning embracing a dermatitis as one manifestation. When skin diseases are to be connected with the use of water it is usually true that irritating soaps and other toilet articles are more to blame than the water itself.

#### UNILATERAL CLUBBING OF FINGERS

*To the Editor*—Could you put me in touch with any information relative to clubbing of the fingers and distortion of the finger nails occurring unilaterally? I am inclined to believe that this is an unusual condition, and if you can inform me where I can obtain any reference or literature I will be greatly obliged.

GROSBECK WALSH MD Fairfield Ala

*ANSWER*—Unilateral clubbing of the finger tips is very rare. Any case listed in this category must be of some duration for Julius Heller (Handbuch für Haut- und Geschlechtskrankheiten Berlin Julius Springer 12:278 1927) mentions the fact that the deformity begins on one side in most cases later involving the other extremities.

Loucaides has recently reported a case of unilateral club fingers (Einseitige Trommelschlegelfinger *Ztschr f klin Med* 121:724 1932) and has found but seventeen previously recorded

cases, all caused by one sided aneurysms except one in which there was a long standing dislocation of the shoulder joint. The case reported by Loucaides was of particular interest because the deformity of the fingers, with enlargement of the hand and local nervous symptoms, did not appear until the aneurysms, which involved the aortic arch and the right subclavian artery, were complicated by a suppurative chronic bronchitis.

The deformity is due to edema of the soft tissues at the proximal ends of the distal phalanges. This lifts the proximal end of the nail and causes it to grow downward and forward over the end of the finger. The obstructed circulation results in overgrowth of horn and the nail becomes thick. The blood vessels are dilated and the lunula tends to disappear. The skin proximal to the nail is distended and glossy and this end of the nail rests on a soft cushion, on which it can be rocked by slight pressure. The whole phalanx including even the bone in severe cases, becomes enlarged to resemble the head of a drumstick.

The literature of one sided club fingers is listed by Loucaides.

#### INJECTION TREATMENT OF HYDROCELE

*To the Editor*—Is it practical to use sodium morrhuate 5 per cent to obliterate the sac of a hydrocele? The patient is an elderly man in poor physical condition. Aspirating the hydrocele causes it to refill quickly. If it is practical, please give details of technique. Please omit name.

MD New York

*ANSWER*—Before deciding on the injection treatment of a hydrocele, one must make certain that there is no communication with the peritoneal cavity, such as occurs in the congenital type of hydrocele, and that there is no associated inguinal hernia. The latter may become irreducible if the hydrocele is obliterated. Furthermore, a gonorrheal tuberculous or non-gonorrheal epididymitis and a tumor of the testicle must be excluded. Such lesions might become palpable after the sac has been tapped. If the foregoing factors in producing a symptomatic hydrocele are excluded and the patient is not fit for operation, an aspiration of the sac may be done. The scrotal skin is carefully sterilized with mercurochrome or acriflavine hydrochloride, a dermal wheal is produced with 1 per cent procaine hydrochloride, and a spinal puncture needle is used to tap the sac, puncture of the testicle being avoided. The fluid should be completely withdrawn, care being taken that the needle still remains free in the cavity and is not caught in the wall of the sac. The sclerosing substance is now injected, the needle withdrawn and the site of puncture sealed with collodion.

The sac may be gently massaged to insure better distribution of the irritating substance. Solutions used for this purpose include from 0.5 to 2 cc of pure phenol (carbolic acid) or 10 per cent gumme and ethyl carbamate solution, not exceeding 4 or 5 cc for the first time. A 5 per cent sodium morrhuate solution is used by Porritt (*Proc Roy Soc Med* 24:971 [May] 1931), who washes the sac first with sterile water and then injects from 4 to 5 cc of the solution. It would seem more logical to use a 10 per cent solution for this purpose. Following the injection, the scrotal sac is supported. It may get tender and swell. A second injection is usually necessary after a week or two. Great care should be exercised not to produce an infection of the hydrocele.

#### VERTIGO FROM WORK WITH HANDY REPAIR CEMENT

*To the Editor*—I have a patient whose chief complaint is vertigo at irregular intervals. He spends about six hours a day working and handling handy repair cement. He informs me that this contains butyl acetate, ethyl acetate and acetone. He inhales more or less fumes during the day. Are these apt to be injurious and if so what symptoms do they produce?

HENRY B SMITH MD Hempstead N Y

*ANSWER*—The constituents of "handy repair cement" are not constant among the several manufacturers and for any given manufacturer it is probable that the formula changes from time to time depending on market conditions. At least in times past, benzene has been much used and probably is used at the present time. If in fact, benzene was employed as an ingredient, vertigo along with various other manifestations such as leukopenia is a reasonable result of exposure. If, on the contrary, the cement contains nothing more than butyl and ethyl acetates along with acetone, extensive harm is not a prospect. The action of these substances in small quantities is usually limited to minor degrees of irritation of the eyes, skin and respiratory tract. Headache and nausea are possibilities and the occurrence of vertigo is not beyond the bounds of expectancy.

## SALT LOSS IN PERSPIRATION

To the Editor—Will you kindly advise us as to the amount of salt required to compensate for the loss by perspiration in men in industrial plants. Also advise as to the best method of administration and also whether salt in tablet form is available and if so where it may be obtained. Please omit name.

M D, Illinois

ANSWER—The practical aspects of this subject are covered in an article, "Heat Cramps in Industry Their Treatment and Prevention by Means of Sodium Chloride" by Dr. Donald M. Glover (*J Indust Hyg* 13 347 [Dec] 1931). Glover illustrates a machine for dispensing 16 grain (1 Gm) sodium chloride tablets made by the McKesson Hall Van Gorder Company, Cleveland, and the Fairway Laboratories, Belleville, Ill. Workers in the steel and aluminum industry, under extreme conditions of heat, took one of the tablets with each drink of water and usually drank two or three times an hour while doing muscular work. It is apparently safe to allow workers to eat as much salt as they feel that they require, and the material should be made completely available if the preventive measure is to be effective.

## TREATMENT OF TABES

To the Editor—Kindly outline treatment for a late stage of syphilis in a man aged 42 complaining of imperfect erection and diminished libido. He has a three plus Wassermann reaction, rigid pupils, irregular knee jerks and some urinary incontinence. Five years ago he had a course of intravenous and intraspinal arsenicals. He was under treatment for two years under different physicians and by different methods. For the past two or three years he has had no medication. He refuses a spinal puncture because of previous painful experiences. Please omit name.

M D, Wisconsin

ANSWER—The data suggest that this patient has a deterioration of the posterior column (tabes), which accounts for the pupillary changes, the incontinence and the diminished knee jerks. If he has no cardiac lesion and is otherwise in fair health, it is not unlikely that a course of malarial treatment will be of great benefit to him.

The lumbar puncture, however, should be repeated, as it is an excellent guide not only to diagnosis but as a criterion for recovery following the malarial therapy. If done properly, it should give rise to little or no pain.

## MEASURING PRESCRIPTIONS

To the Editor—I have read with much pleasure the article on the Therapy of Cook County Hospital in *THE JOURNAL* for June 2 but was rather surprised at the form of the prescriptions. As I read them one dose is supposed to be contained in 4 cc. If these are administered in the wards does it imply that doses of medicine in the wards are measured in teaspoons rather than in measuring glasses and if they are used for outpatients why is it assumed that a teaspoon holds 4 cc? The average teaspoon at least in this part of the country holds from 5 to 6 cc.

J. M. HAYMAN JR., M D, Cleveland

ANSWER—The criticism is well taken. Unfortunately, the Cook County Hospital has been, up to the present, committed to the old system of weights and measures and is equipped with medicine glasses graduated according to the old one drachm equals one teaspoonful. This series represents an attempt to substitute the metric for the old system. It would be practically impossible, if for no other than financial reasons, to discard all the old measuring devices and introduce new ones, hence this compromise.

## EFFECT OF COMPOUND SOLUTION OF IODINE ON BASAL METABOLIC RATE

To the Editor—Please tell me whether compound solution of iodine (Lugol's solution) will decrease the basal metabolic rate when this increased rate is due to taking thyroid, i. e. at a more rapid rate than by simply discontinuing thyroid? Please omit name.

M D, Virginia

ANSWER—The administration of compound solution of iodine has no effect on the increased basal metabolic rate caused by the taking of thyroid extract or thyroxine, in rabbits (Sturgis, C. C., and others, *J Clin Investigation* 2 289 [Feb.] 1925), in dogs (Kunde, Margaret M., *Am J Physiol* 82 195 [Sept.] 1927) or in man (Carson, D. A. and Dock, William, *Am J M Sc* 176 701 [Nov.] 1928). This is explained by the authors last mentioned as being due to the fact that the site of action of the iodine is on the thyroid gland itself rather than on the thyroid products. However, Abelin has reported that the elevation of the basal metabolic rate caused by feeding thyroid substance to rats is decreased when diiodotyrosine is given in addition (*Biochem Ztschr* 233 483, 1931, *Klin Wchenschr* 10 2201, 1931).

## TELEPHONE NOISES AND AUDITORY DISTURBANCES

To the Editor—I have a patient who claims that following the picking up of a telephone receiver and the cracking that occurs as the operator rings the number his ear drum burst. Otoloscopic examination did show a ruptured ear drum. He is at present suing the telephone company for the accident and impaired hearing. Can you cite any similar cases in medical literature? Is such an occurrence possible?

MILTON WOLPERT, M D, Chester, W. Va.

ANSWER—It seems rather strange that vibrations of the telephone receiver diaphragm should cause such a change in the air pressure of the external auditory canal that rupture of the drum membrane would ensue. The only reference in the literature dealing with changes in the ear due to the use of a telephone is Moriez, A., *Auditory and Neurologic Disturbances Caused by Traumatizing Telephone Noises. The Nature of the Noises and Mode of Operation*, *Rev d'oto neuro ophth* 2 171 (March) 1933.

## VALUE OF SYPHILIS VACCINE NOT ESTABLISHED

To the Editor—In *THE JOURNAL*, April 28, page 1444 is a short abstract of an article entitled *Spirochete Vaccine in Treatment of Syphilis* from the *Dermatologische Wochenschrift*. Kindly give the status of this mode of treatment in the United States. Has it been confirmed to be effective? Please state whether that vaccine can be obtained in the United States and if so, where, if not, where can it be obtained in Germany?

AARON I. LEVINS, M D, Madison, N. Y.

ANSWER—The treatment in question is purely experimental. It has no definite standing in this or any other country. It has not been confirmed as effective. There is no place in this country where the vaccine used by the author mentioned in the question (Neuber, E., *Therapeutic Experiments with Living Spirochetes in Cases of Early Syphilis*, *Dermatol Wchenschr* 98 229 [Feb. 24] 1934) can be obtained, and so far as we know the vaccine is not for sale in Germany either.

## THERAPEUTICS OF GOLD TRIBROMIDE AND OF IRON PREPARATIONS—ARSPHENAMINE AND TEETH

To the Editor—1. I have been using gold tribromide in whooping cough. The patient's parents are so enthusiastic that I find they are renewing the prescription for all sorts of coughs. Is there any danger to the patient in a prolonged use of this drug? Is there any danger in the staining of the teeth? 2. Do the following preparations imperil the teeth: syrup of ferrous iodide, Syrup of Cupriferrum (Squibb)? 3. Does present medical opinion favor the ferric or the ferrous salt in the treatment of secondary anemia? 4. Is arspenamine in glycerin used locally for Vincent's angina, injurious to the teeth? Kindly omit name.

M D, New York

ANSWER—1. No

2. No

3. Ferrous salts

4. No

## TRANSMISSION OF RABIES

To the Editor—A patient of mine was bitten by a pet dog after the dog had been given a dose of rabies vaccine. At the time the bite was inflicted the dog was quite ill as a result of the vaccination. Is there any possibility that such a bite might transmit rabies? If this is published kindly omit name.

M D, North Carolina

ANSWER—In all probability the vaccine used was killed before injection either by phenol or by chloroform and consequently there would be no danger of the transmission of rabies by the vaccine. It must be noted that in a case like the one cited the question arises whether the dog could have been suffering from rabies at the time of its bite.

## PROPER CARE OF ORBIT WITH GLASS EYE

To the Editor—I have read what you have to say on the proper care of the orbit with a glass eye (*THE JOURNAL*, June 23, p. 2135). Antiseptics employed in the eye will not prove of value in this case if the glass eye is several years old and should have a crevice or break in it. I have seen several cases and securing a new eye cleared up the condition. I tried everything you mention with no results. I would advise getting a new glass eye for that man.

J. O. CHIAPPELLA, M D, Chico, Calif.

## PSITTACOSIS

To the Editor—I note in the answer to the query on psittacosis (*THE JOURNAL*, May 5, p. 1521) the statement that in the majority of cases psittacosis appears to have been transmitted from sick parrots. While this was true formerly the cases in this country during the past two or three years have been in the majority of instances I believe from love birds raised in California. STANLEY H. OSBORN, M D, Hartford, Conn., Commissioner of Health, State of Connecticut.

## Book Notices

**Allergy in General Practice** By Samuel M Feinberg M D F A C P  
Assistant Professor of Medicine and Attending Physician in Asthma and  
Hay Fever Clinic Northwestern University Medical School Cloth Price  
\$4.50 Pp 339 with 24 illustrations Philadelphia Lea & Febiger  
1934

Here is a practical handbook in allergy compiled by a  
student The first chapter is an interesting historical orienta-  
tion of the subject The second summarizes the immunologic  
arguments The third describes asthma clinically In the next  
four chapters the author classifies, analyzes and sifts every  
scrap of material on the approach toward a solution of asthma  
Three chapters are devoted to hay fever It is not disparag-  
ing to say that the keystone of this arch-allergist's credo is  
Durham's chapter on pollen Sheer merit makes this section  
stand out It is the most concise account of the national situa-  
tion thus far presented It can be appreciated only by the  
practicing allergist, who finds his every quest in the clinical  
geographic importance of pollens now ended Every allergist,  
hay fever treating doctor and patient will henceforth be  
indebted to Mr O C Durham, chief botanist of the Abbott  
Laboratories, for the practical application of the mass of  
authoritative botanic information that he has made available  
so succinctly for clinical purposes In another chapter are  
grouped the problem children of allergy, namely, hyperesthetic  
rhinitis, urticaria, angioneurotic edema eczema contact der-  
matitis, gastro-intestinal allergy, allergic headache and other  
possible allergic syndromes such as epilepsy, urinary distur-  
bances, joint manifestations, eye conditions, vascular diseases  
and malnutrition The author has omitted a promising method  
of direct nasal testing which will solve a certain percentage  
of cases of hyperesthetic rhinitis not benefited at present He  
must learn that infantile and childhood eczema is not all food  
allergy There is a distinct group on an inhalant basis He  
should know that many so-called eczemas and neurodermatitides  
occurring with pollinosis clear under pollen treatment and that  
these are distinct from the pollen oil sensitive group The  
last chapter is a compressed but comprehensive dry clinic  
illustrating the application of the allergic approach and meth-  
ods of treatment

The philosophy of such a compilation involves an over-  
whelming seriousness of purpose and a totally absent sense of  
humor The older authorities in the subject have been too  
busy pushing out the borders of knowledge to write primers  
However, every allergist of note has contributed to the authori-  
tativeness of the volume, and Feinberg makes generous and  
systematic reference to them

The author belongs to a group of self taught allergists He,  
at least, has achieved justification for the judiciously serious  
men behind which he masks his novitiate A hypercritical  
attitude toward all that possesses the daring and dash of uncon-  
ventional thought is the defense mechanism of the uninitiated  
He seems in constant fear lest his overvalued lack of formal  
training betray him and throughout the book there are qual-  
ifying clauses half-hearted acquiescences and the "yes and then  
again no" point of view The compilation is simple and ele-  
mentary but eminently practical as a beginner's handbook  
This book will remain the model for allergy handbooks for a  
long time

Die akuten Zivilisationsseuchen Masern Pocken Keuchhusten Scharlach Diphtherie epidemische Kinderlähme ihre Epidemiologie und Bekämpfung Von Dr. B. de Rudder o. b. Professor Direktor der Universitäts-Kinderklinik Greifswald Paper Price 16 marks Pp 286 with 49 illustrations Leipzig Georg Thieme 1934

The purpose of this book is to summarize in a practical way existing knowledge of the modes of spreading and the prevention of measles, smallpox, whooping cough, diphtheria, scarlet fever and infantile paralysis. These six diseases are regarded as the major epidemics of our times among civilized people. On account of their high contagiousness, measles, smallpox and whooping cough are grouped together. In the spread of these diseases the patient plays the most important part by far and consequently the methods of prevention are different in some respects from those used against diphtheria, scarlet fever and infantile paralysis, in which the carrier plays the essential part in spreading the infection. The epidemiology, the endemology and the principles and methods of preventing these diseases are discussed thoroughly and competently. The teachings are sound and progressive. The writing is rather cumbersome, with long and complicated sentences. The author does not seem to be familiar with the most recent American developments in the prevention of diphtheria and scarlet fever, but there is no doubt about his full acceptance of the fundamental principles on which the preventive measures are based. The book will interest all who are concerned with the six diseases to which it is devoted. There is no other book available at present that deals with their epidemiologic and preventive aspects in as thorough a fashion.

Archiv und Atlas der normalen und pathologischen Anatomie in typischen Röntgenbildern Die Krankheiten der Nasennebenhöhlen und des Ohres im Röntgenbild Von Priv. Doz. Dr. med. Richard Mittermaier Oberarzt der Klinik. Ergänzungsband XLV Fortschritte auf dem Gebiete der Röntgenstrahlen Herausgegeben von Prof. Dr. Grashey Paper Price 25 marks Pp 141 with 213 illustrations Leipzig Georg Thieme 1934

As the author himself states, this atlas is to serve not only roentgenologists but otolaryngologists who have thus far been unable to develop a wide experience with the subject of roentgenology and its results in diseases of the nasal accessory sinuses and the ear. Furthermore, it is to serve them as a basis for their own studies. The work has been developed from actual practice and is written for practitioners. With the exception of a few pictures furnished by Professor Grashey, they are all derived from roentgenograms made in the x-ray department of the university ear, nose and throat clinic at Freiburg in Breisgau. The work is divided into two sections, of which the first deals with the various diseases of the nasal accessory sinuses and the second one with those of the ear and the temporal bone. The reproductions of the films are clear, and the descriptions of the conditions found clinically are concise and informative. Accompanying the films of the nasal accessory sinuses, outlying diagrams are furnished which greatly aid in their complete understanding. There is no text other than that of the short descriptions accompanying each picture. The work is well done and should prove of great value both to roentgenologists and to otolaryngologists in their daily practice.

Les phlegmons de la loge amygdalienne. Diagnostic et traitement. Par G. Canuzy, professeur de clinique oto-rhino-laryngologique à la Faculté de médecine de Strasbourg et P. Daull, chef de clinique oto-rhino-laryngologique à la Faculté de médecine de Strasbourg Paper Price 16 francs Pp 137 with 35 illustrations Paris Masson & Cie 1934

This little monograph discusses, in detail, infections of the tonsillar fossa, the authors preferring that term to those of peritonsillitis or paratonsillitis. The normal and the pathologic anatomy of the tonsillar fossa are first discussed in considerable detail, and the authors lay considerable stress on the details of the supratonsillar space. The etiology of the various infections in and about the tonsils is then described. In the chapter on clinical study, attention is called to the fact that in the posterior type of infection of the tonsillar fossa there is absence of trismus. In the next section the subject of the local complications in the pharynx, larynx and peritracheal tissues is discussed. Under the heading of "Diagnosis," the exploratory puncture of infected tissue is described. The next

chapter deals with the medical treatment, including local applications of epinephrine, chloride of zinc, tincture of iodine and light scarifications of the soft palate and pillars of the fauces. The injection of electrargol is mentioned as well as that of bacteriophage. The authors also suggest, in the general medical treatment, colloidal therapy in the way of injections of collargol, electrargol, colloidal gold and omnadin (a proprietary mixture of partial antigens). They also mention injections of stock vaccines, auto vaccines, and injections of the patient's own blood. The surgical treatment consists in incision of the suppurative area or in removal of the tonsils. The latter procedure has for some time been used quite extensively by American laryngologists.

This brochure is logically and well written, and the illustrations aid greatly in the elucidation of the text. The work is timely and will well serve those who are interested in the infections of and complications involving the tissues in and about the tonsils.

A Study of the Ionization Method for Measuring the Intensity and Absorption of Roentgen Rays and of the Efficiency of Different Filters Used in Therapy. By Robert Thoræus Fil. Lic. Kalm. Akademisk Avhandling som med Tillstånd av Vinnande av Filosofisk Doktorgrad Uppsala Acta Radiologica Supplementum XV Paper Pp 88 with 40 illustrations Stockholm F. Englund's Boktryckeri a. B. 1932

In this monograph, Thoræus reports on some filtration properties of various metals checked against five qualities of radiation and illustrates in charts and tables his results. The efficiency of various metals as filters is discussed next and he presents data to assist one in selecting the best filter for a certain purpose. His new "tin filter" is described, which takes the place of 2 or 3 mm of copper, producing hard radiation with the additional advantage of not decreasing the intensity. The monograph closes with some studies made in the water phantom on the relative roles of true absorption and back-scattering. The volume is important in helping to solve many of the puzzling problems of filtration and dosage in roentgen therapy.

National Policies Affecting Rural Life. Proceedings of the Sixteenth American Country Life Conference. Blackburg, Virginia, August 1-4, 1933. Cloth Price \$2 Pp 152 Chicago University of Chicago Press for the American Country Life Association 1934

The addresses reported include "World Agriculture" by Henry A. Wallace, "The National Policy Needed" by Norman Thomas, "Agricultural World Economy" by Wallace McClure, "International Debts and Monetary Policies" by Leo Pasvolosky, and "World Trade Barriers" by Lynn R. Edminister. There is a round table report on "Rural Health and Welfare" by Katherine F. Lenroot of the Children's Bureau which states the problem and summarizes conditions and the institutions supplying medical care in rural neighborhoods. The participation of the federal government in state and local welfare services is urged.

The Chemistry of Flesh Foods and Their Losses on Cooking. By R. A. McCance and H. L. Shipp. Medical Research Council Special Report Series No. 187. Paper Price 2s 6d Pp 146 with 36 illustrations London His Majesty's Stationery Office 1933

This report gives the chemical composition of cooked meat, poultry and fish. All types of cuts were used and methods of cooking suitable for each were employed. The analyses are quite complete in that they include protein and nonprotein nitrogen, fats, carbohydrates, and the elements sodium, potassium, calcium, magnesium, iron, phosphorus and chlorine. The methods of analysis used are given in detail. Among the observations made in connection with the study the following are of special interest. The losses in weight, water and salts incurred in cooking meat are the same, regardless of the temperature of the water when the meat is placed in it. The losses in salts and protein in meat roasted in an uncovered pan are appreciably less than in that roasted in a covered pan, owing to the fact that in an open pan much of the water expressed from the meat during shrinking is evaporated, leaving the salts and protein that were in solution in the expressed water concentrated at the surface of the roast. The shrinkage in meat cooked by steam at high temperature as in a pressure cooker is slightly greater than in that cooked by steam at 100 C.

**A New Physiological Psychology** By W Burrige DM MA Professor of Physiology Lucknow University With a foreword by Sir Leonard Hill MB LL D FRS Cloth Price \$3 Pp 158 with 6 illustrations. London Edward Arnold & Company 1933

This book presents a theory of the action of the nervous system. The author believes that the end organs and central neurons are rhythmic and that the problem is one of colloidal chemistry. Muscle and nerve tissue form two sources of potential energy, which are called kinesiphores. A stimulus does not detonate the nervous system but acts rather as an anabolic agent. The author holds that this does away with explanations which are dependent on the function of the synapse. He links his theory with Freudian psychology, particularly from the angle of the pleasure-pain principle, which he says is the functioning of the relationship between the two kinesiphores. Chapters are devoted to the relationship between this author's theory and the knee jerk, memory, dreams, convulsive states and other rather isolated psychologic phenomena. While the theory itself does not seem far fetched, the author's interpretations of the psychologic phenomena do appear naive. His book is not convincing.

**The Common Diseases of the Skin. A Handbook for Students and Medical Practitioners** By R Cranston Low MD FRCP Consulting Physician to the Skin Department Royal Infirmary Edinburgh Second edition Cloth Price 12/6 Pp 317 with 150 illustrations Edinburgh & London Oliver & Boyd 1934

This is a short, concise exposition of dermatology written primarily for the student. The illustrations are carefully selected and many of them are in colors. The drawings illustrating the microscopic pathology of the more important diseases have been well executed by the author himself. The text represents the clinical conception and therapeutic methods in vogue in the present day Edinburgh school of dermatology. No attempt has been made to include syphilis, the excuse being given that this subject is adequately taken up in textbooks on venereal diseases. It is hoped that future editions will include this important subject. Medical students and practitioners will find this volume useful for a rapid review of dermatology.

**Cholera. A Manual for the Medical Profession in China** By Wu Lien Teh J W H Chun R Pollitzer and C Y Wu Cloth Price \$3 Pp 197 with 24 illustrations Shanghai National Quarantine Service 1934

China is sometimes pictured as a country so backward that only a helping—or forcing—hand from the outside can bring it into the fellowship of civilized nations. No one, however, can read this book by Chinese authors on cholera (*huo-luan*) without realizing that strong forces are at work from the inside. The discussion of one of the most serious diseases in the Orient is on a high level, it is unpretentious but is lucid, accurate and well abreast of current knowledge. The importance of clean water supplies in the control of cholera is clearly recognized and other factors are discussed with complete understanding and good sense. Many Western readers will find the chapter on the history of *huo-luan* in China of particular interest.

**Ein Methode zur Messung von Röntgen Radium und Ultrastrahlung nebst einige Untersuchungen über die Anwendbarkeit derselben in der Physik und der Medizin** Mit einem Anhang Enthaltend einige Formeln und Tabellen für die Berechnung der Intensitätsverteilung bei  $\gamma$  Strahlungsquellen. Av Rolf M Sievert Fil Lic Stockh Akademisk Arhåndling som med Tillstånd för Vinnande av Filosofisk Doktorsgrad Upsala Acta Radiologica Supplementum XII Paper Pp 207 with illustrations Stockholm Kungl Boktryckeriet P A Norstedt & Söner 1932

In this monograph Sievert discusses the mathematics and physics of ionization measuring devices and from these considerations favors condenser-chamber systems the advantages and disadvantages of which he analyzes in considerable detail. Sievert has developed many condenser-chamber measuring devices useful not only in measuring the various types of rays but also gamma rays. In this way the daily treatments at Radiumhemmet can be checked up and also compared with the techniques used in other clinics. By the use of these condenser-chambers Sievert is enabled to measure not only surface doses but also those in the various body cavities. The consideration of the physics and construction of these chambers can be followed easily by any one having a meager knowledge

of mathematics and physics. The monograph has a bibliography of 171 references, 286 studies and some photographs of these ionization chambers and their accessories and closes with tables of the energy distribution of gamma radiation. It is an excellent presentation, which should be of interest to all those whose work involves the study of doses in radiotherapy.

**De la psychose paranoïaque dans ses rapports avec la personnalité** Par le Docteur Jacques Lacan Paper Price 50 francs Pp 381 Paris Librairie E Le François 1932

This is a highly technical discussion of the subject of the paranoid psychoses, giving a lucid and exhaustive exposition of the teachings of Kraepelin, Serieux and Capgras, Kretschmer, Kehrler, Lange and others. There is also an excellent report in detail of a case. The third and final part of the book discusses, in a manner that is admittedly speculative, the significance of the paranoid states, based mainly on a psychoanalytic interpretation of the delusional contents. The views offered are largely repetitions of authoritative statements rather than original concepts. The book will be of little interest to the general physician, but it contains much of value for the graduate student and the psychiatrist.

## Medicolegal

**Workmen's Compensation Acts. Hernia Attributed to Overexertion**—In the course of his employment, Feb 4, 1932, Peterson and two fellow workmen moved a metal tank, weighing about 5 tons, along a concrete floor, by means of steel rollers placed under it and shoved forward by steel pinch bars 6 feet in length. This work required much exertion and energy in pulling and lifting. At times the bars would slip, causing strain to the bodies of the workmen. When the noon hour came, Peterson, who had theretofore been an active man and quick in his movements, was observed to leave his work very slowly. He made no statement at the time of having been injured, but his face was purple or bluish. Between 12 30 and 1 o'clock he was heard to call for help and was found in his automobile, parked nearby, sitting or lying on the back seat, with his feet over the back of the front seat. He was groaning and gave evidence of great pain. A fellow workman drove him to a hospital, where it was discovered that Peterson was suffering from a strangulated hernia. He was doubled up in pain so that he could be examined only with difficulty, his pulse was rapid, his body was cold and clammy. At the time of the operation, the hernia had increased to the size of a baby's head. The operation disclosed that Peterson had a large thin sac filled with about a quart of blood, and that about a foot or foot and a half of fairly dark bowel had descended into the scrotum. Five days later, Peterson developed a paralytic ileus and death followed. His widow instituted proceedings under the workmen's compensation act of Utah and despite the fact that neither the employer nor his insurance carrier presented any evidence, the commission found that "there was no competent evidence to establish that the decedent met with an accident or that his death was the result of an accidental injury." From a denial of compensation the widow appealed to the Supreme Court of Utah.

The only question here present, said the Supreme Court, is whether the evidence that was produced at the hearing was sufficient to justify an award of compensation. In the opinion of the court there was sufficient competent evidence of an accidental injury. Peterson's family physician, who assisted in the operation testified that he had never treated Peterson previously for hernia and said "if I ever saw a traumatic hernia in my life that was a typical traumatic hernia." The manner in which the employee left his work, continued the court, the discolored appearance of his face at the time, the indications of severe pain and suffering when found in the automobile, and the rapidly developing hernia, all pointed directly and logically to an industrial injury as the cause of Peterson's trouble. The declarations and statements made by the deceased to his physician, before the operation, that he was

lifting on a boiler five or ten minutes before he left work and while lifting felt "terrible pains," were admissible under the rule stated in 3 Jones Comm on Evidence (2d Ed) 2234

Where it appears that the physician testifying was called by the injured person in his ordinary professional capacity and for purposes of securing relief from pain and for medical treatment, and there are no circumstances casting suspicion on the genuineness of the utterance, all statements of symptoms and sufferings whether past or present and though involving statements as to the nature of the accident, if necessary to diagnosis by the physician may be testified to by him. On the other hand where a physician examines an injured person for the express purpose of testifying as to his physical condition even declarations of present pain made by the patient to the physician have been held inadmissible.

To establish the fact of a traumatic hernia, it was contended, it was necessary to show that the injury caused immediate disability by reason of pain at the time of the accident, and that where the accident is followed by a later development of hernia, the accident must be regarded as the occasion rather than the cause of the injury. But, said the Supreme Court, in the present case the effect was immediate. It was no less immediate because the condition of the deceased grew progressively worse during the two hours between noon and the time the operation was performed. The medical testimony indicated a traumatic strangulated hernia of recent origin. There was nothing to indicate that Peterson had a previous hernia or that there were other predisposing causes. That overexertion may cause accidental injury or death, continued the court, is no longer open to serious question. The only reasonable or permissible inference from the evidence in this case is that the hernia was caused by strain or overexertion while moving the tank. The court accordingly set aside the findings and the decision of the commission and remanded the cause for further proceedings.—*Peterson v Industrial Commission of Utah (Utah)*, 27 P (2d) 31

**Malpractice Liability for Roentgen Burn**—No presumption, says the Court of Appeals of the District of Columbia, of want of skill or care ordinarily arises from the fact that medical treatment is unsuccessful. But evidence that a physician administered roentgen treatment to a patient without remaining in the room or within hearing, which treatment resulted in a burn, warrants a finding of negligence, unless satisfactorily explained. It is for the jury to determine the issue from all the evidence presented. In such a case it constitutes error for the trial court to direct the jury to return a verdict for the defendant-physician.—*Grubb v Groover (District of Columbia)* 67 F (2d) 511

## Society Proceedings

### COMING MEETINGS

- American Academy of Ophthalmology and Otolaryngology Chicago Sept 9-14 Dr William P Wherry 107 South 17th Street Omaha Executive Secretary
- American Association of Railway Surgeons Chicago August 20-22 Dr Louis J Mitchell 21 East Van Buren Street Chicago Secretary
- American Congress of Physical Therapy Philadelphia Sept 10-13 Dr Nathan H Palmer 921 Canal Street New Orleans Secretary
- American Public Health Association Pasadena Calif Sept 3-6 Dr Kendall Emerson 50 West 50th Street New York Executive Secretary
- Colorado State Medical Society Colorado Springs Sept 19-22 Mr Harvey T Sethman 537 Republic Bldg Denver Executive Secretary
- Idaho State Medical Association Lewiston Sept 7-8 Dr Harold W Stone 105 North Eighth Street Boise Secretary
- Michigan State Medical Society Battle Creek Sept 12-14 Dr F C Warnshuis 148 Monroe Avenue Grand Rapids Secretary
- National Medical Association Nashville Tenn August 13-18 Dr C A Lanon 431 Green Street South Brownsville Pennsylvania General Secretary
- Nevada State Medical Association Reno Sept 21-22 Dr Horace J Brown 120 North Virginia Street Reno Secretary
- Northern Minnesota Medical Association Brainerd Sept 10-11 Dr Oscar O Larsen Detroit Lakes Secretary
- Pacific Northwest Orthopedic Association Seattle Sept 1 Dr J C Brugman 1215 Fourth Avenue Seattle Secretary
- Western Branch of American Public Health Association Pasadena Calif Sept 3-6 Dr W P Shepard 600 Stockton Street San Francisco Secretary
- Washington State Medical Association Spokane Sept 10-13 Dr Curtis H Thomson 1305 Fourth Avenue Seattle Secretary
- Wisconsin State Medical Society of Green Bay Sept 12-14 Mr J G Crownhart 119 East Washington Avenue Madison Secretary

## MISSOURI STATE MEDICAL ASSOCIATION

Seventy Seventh Annual Meeting held in St Joseph Mo  
May 7 to 10 1934

DR W L ALLEE, Eldon, in the Chair

### The Management of Blood Diseases

DRS J H MUSSEY and D O WRIGHT, New Orleans

Instead of grouping the so called blood disorders on the basis of the etiology, the morphology of the blood cells or any of the accepted classification, we have presented as a group certain blood disorders that are benefited by several forms of therapy.

1 Blood conditions benefited by vitamin therapy: pernicious anemia, sprue and pernicious anemia of pregnancy, three conditions which are alleviated by vitamin B therapy.

2 Blood conditions benefited by drugs: four anemias that are materially helped by the administration of iron in full and adequate doses—idiopathic hypochromic anemia, normocytic anemia, sideroblastic microcytic anemia and the anemia of pregnancy, here also listed polycythemia vera, which may be treated successfully with phenylhydrazine, agranulocytic angina, which apparently may be cured by pentnucleotide, and hemophilia, which is included for the purpose of discussing a form of treatment which we do not think beneficial.

3 Blood conditions benefited by radium or roentgen therapy: the two types of chronic leukemia that definitely are ameliorated by irradiation, though physical measure does not produce a cure but does relieve symptoms for a time at least and prolongs life.

4 Blood conditions benefited by splenectomy: three genetically dissimilar dyscrasias of the blood, which, however, are to all intents and purposes cured in many instances by removal of the spleen. These various therapeutic measures may not be curative in the sense that they remove the underlying cause, but at least they are definitely capable of relieving the patient.

### Fibromas of the Small Intestine with Intussusception

DRS WALLIS SMITH and GUY D CALLAWAY, Springfield

In two cases of fibromas of the ileum the symptoms and the clinical examination suggested acute intestinal obstruction. Intussusception was present in each and the tumor was found in the distal portion of the telescoped bowel. One of the patients gave a history of lower abdominal pain, cramping, distention and constipation for a period of several months before intussusception occurred. The onset of symptoms in the other case was sudden and acute but diminished after a few hours. Resection of the intussuscepted portion of the bowel was done in the first case but only ileotomy was required in the second. Microscopic examination showed the tumors to be fibromas. The patients recovered. Thirty eight instances of fibromas of the small intestine were found in the literature. Some of the tumors were discovered at autopsy but most of them were discovered during operation for acute intestinal obstruction. Intussusception was the usual complication producing a complete occlusion of the bowel. Diagnosis is difficult. Roentgen therapy offers the best possibilities but at this time it is seldom possible to differentiate occlusion due to intraluminal tumors from obstruction due to other lesions. A correct diagnosis is usually made at the time of the operation but all intestinal tumors should be examined microscopically. The only treatment required in uncomplicated cases of fibroma of the small intestine is ileotomy and removal of the tumor and its base. If an irreducible intussusception is present or gangrene has developed resection of the bowel is necessary. The mortality rate after ileotomy is low. It increases in the group of cases in which resections are done, being greatest in the group of patients in whom gangrene develops prior to operation.

### Tertian Malaria with Unusual Type of Skin Manifestations

DR A GLENN DAVIS, Kirkwood

A white girl, aged 12 years, seen Sept 9, 1933 had had apathy, weakness, loss of weight and anorexia for six weeks. Chills, rises of temperature and diarrhea had appeared, three weeks previously. The parents had given the child patent remedies and the chills ceased after two weeks, but the occurrence of fever at intervals of forty-eight hours, as well as severe diarrhea persisted. Bilcs, about 6 mm in diameter, appeared September 9 and were distributed

over the entire body excepting the soles and the palms. No papules or pustules were seen at any time. To the naked eye, the small round lesions resembled the microscopic appearance of stained small lymphocytes except as to color. The dark portion of the lesions, corresponding to the nucleus of a stained cell, was red. It was in the center and located deeply under the thin epidermis overlying the lesions. The periphery of the lesions, corresponding to the cytoplasm of a stained lymphocyte, was light in color and narrow. The lesions were filled with a colorless serous fluid. The blood smear showed innumerable plasmodia. The hemoglobin was 70 per cent. The urine showed a faint trace of albumin and numerous pus cells. Atabrine was given in the recommended dosage. The diarrhea was checked after a period of twenty-four hours. The skin lesions disappeared by a gradual decrease in the size and in the depth of color until by end of the fifth day only smooth pink areas marked the sites of the lesions. There was no fever after the second day of treatment. The first impression was that the patient might have hemorrhagic smallpox. Closer observation of the lesions, however, revealed the absence of umbilication. In December I saw the patient again and found that there was marked and conspicuous pitting where the lesions had been, especially in the regions of the face and neck. That the lesions were definitely a manifestation of the malarial infection is borne out by the prompt response to specific therapy.

#### Thyroidectomy for Heart Disease

DR JULIUS JENSEN, St. Louis. Of late, considerable attention has been paid to thyroidectomy for heart disease. The procedure was initiated in 1932 in Boston by Blumgart and his co-workers and is based on the fact that the rate of metabolism is governed by the thyroid gland. If the thyroid gland is removed the metabolic rate is lowered. The lowering of the metabolic rate results in a diminished demand for oxygen by the tissues and thus the demands on the circulation are lessened. While a damaged heart may not be able to carry the full circulatory load of a normal metabolism, it may be able to carry comfortably the load of a lowered metabolism. Thus it may be possible to obtain adequate circulation with a damaged heart by removing the thyroid gland. The preliminary reports from Boston were so promising that the procedure seemed worthy of trial elsewhere. During the last six months Dr. Allen and I have studied a number of cases of heart disease with a view to thyroidectomy for the cardiac condition. Our results have been as promising as those reported from Boston, but the method is still so beset with difficulties that it can not yet be considered safe.

#### Treatment of Angina Pectoris of Effort by the So-Called Cardiac Hormones

DR J. CURTIS LYTER, St. Louis. Heberden, in his masterful description of the angina pectoris of effort, described a patient who was able to prevent his angina by sawing wood for one-half hour each morning. Demoor of Belgium, Haberlandt of Innsbruck, Zwaardemaecker and Zuelzer almost simultaneously conceived the idea that in the skeletal muscles during activity there is produced a substance capable of dilating the coronary arteries. The dilation of the coronary arteries seems to be necessary to supply the cardiac muscle with an adequate quantity of blood during muscular exercise. These authors also believed that during exercise a substance is produced in the liver and pancreas which can not only dilate the coronary arteries but can simultaneously regulate the myocardial contraction tonicity and conduction. Zuelzer produced a substance from the liver called eutonon. Frey and Kraut isolated a substance from the human urine after exercise. They considered it to be of pancreatic origin and named it padutin. Using the skeletal muscles of a calf, Fahrenkamp and Schneider produced a substance which they named lacarnol. Schwartzmann applied the name myaston to a substance which he produced from the same source. Zwaardemaecker produced a substance from the heart muscle and called it automative. He recovered what he thought was a similar substance from the circulating blood. These substances have been called cardiac hormones in continental Europe. Apparently, no two investigators agree regarding the chemical constitution of the substances which have been considered to derive their action from the intermediary products

of nuclear metabolism, from their content of histamine and from their content of adenosine. All investigators agree that they produce a dilatation of the coronary arteries, and an increase in cardiac tonicity.

I have treated twenty-one patients for angina pectoris since August 1933. Seventeen of the number had angina pectoris of effort and four had angina pectoris of decubitus. The patients were given intravenous injections of 1 cc. of padutin daily for from thirty to sixty days. Simultaneously 30 drops of lacarnol was administered three times each day. The patients suffering with angina pectoris of effort were made to exercise in the way of walking after receiving treatment for periods of from ten to twenty days. The walking was stopped with the onset of the least pain. In this way the walks were increased until the patients were able to walk from 3 to 5 miles each day. When this stage was reached, the padutin was administered only twice each week. After a few weeks, both the padutin and the lacarnol were discontinued and the patient was instructed to continue walking for from 3 to 5 miles daily the remainder of his life.

Of the seventeen patients treated for angina pectoris of effort, thirteen have been completely relieved and are now able to walk any distance without anginal pain. Four patients have slight anginal pain after walking one or two blocks. This ceases immediately with rest, following which they can walk for any distance with no discomfort. Of the four patients presenting angina pectoris of decubitus, each has shown marked improvement. They do not have angina while they are at rest but they do experience angina on various degrees of exertion. I feel that by means of the correct use of the cardiac hormones combined with graduated, closely supervised physical exercise, the majority of patients with angina pectoris of effort can be completely relieved of pain, and the majority of patients with angina pectoris of decubitus can be greatly benefited.

#### Skin Testing in Allergic Conditions

DR HERBERT J. RINKEL, Kansas City. Skin testing has generally been accepted as the means of determining the substances to which the patient is sensitive. However, as the knowledge of allergy has increased it has become evident that this procedure is not adequate to discover the etiologic factors. The result has been that some workers have discarded skin testing, others have limited themselves to the use of a selected group of allergens or have sought aid in such measures as elimination diets. Skin reactions occur as the result of contact between a specific allergen (testing extract) and the cellular fixed antibodies in the skin. These antibodies have the ability to sensitize the skin of the nonatopic individual as well as the patient's skin and thus they make indirect testing possible. Skin sensitization is a variable factor, not only in different areas but in the same location over a period of time. It often precedes constitutional sensitivity and may persist after the clinical manifestations of allergy have ceased. Skin testing is further complicated by the number of shock organs that have sensitized the skin to one or more allergens. These allergens have a high degree of specificity for one or more of the various localizations of sensitization. Skin testing cannot be used to determine the presence, the degree or the localization of an allergy. If one will correlate the results of the clinical and laboratory examinations in a large series of cases it will be found that the value of skin testing lies in the average of accuracy, which varies with the different manifestations, being greatest in seasonal hay fever patients.

#### Acute Allergic Abdomen (a Preliminary Report)

DR L. P. GAY, St. Louis. Recent observations by Rowe, Reichet and Vaughn indicate that gastro-intestinal allergy may prove to be the most common manifestation of allergy. The symptoms may be mild or violently acute and may occur with other manifestations of allergy, but at times the abdominal symptoms occur alone. Acute abdominal pain simulating an acute surgical condition of the abdomen has been observed frequently with Henoch's purpura and numerous cases of this type have been treated surgically. The same type of pain has been described in association with other erythematous skin diseases in which urticaria and angioneurotic edema have been included. Abdominal pain has been produced by an overdose

of desensitizing pollen extract, absorption through skin abrasions and food ingestion. The paper deals with allergic episodes including abdominal pain, muscular spasm, elevation of temperature and an instance of leukocytosis. The diagnoses were made by the history and by extra-abdominal symptoms as well as by the physical examination of the abdomen, as ordinary methods of examination and laboratory procedures are of little help. The patients observed made complete recoveries without operation and their symptoms have been reproduced intentionally to make the proof of the condition certain.

#### Treatment of the Underprivileged Patient with Diabetes

DR T. L. HOWDEN, St. Joseph. This group outranks in number any other suffering from the disease. Hospitalization and elaborate equipment are unnecessary in the treatment of diabetes, because the majority of patients with the disease may be managed satisfactorily by the general practitioner. Quantitative analysis of the twenty-four hour urine specimen tells the story and only occasionally is it necessary to determine more than one or two blood sugars.

The basal caloric requirement represents the number of calories used in the trial diet and is determined by the Boothly and Sandiford chart. In proportioning carbohydrates, proteins and fats, 1 Gm. of protein per kilogram of body weight is used. The carbohydrates are placed at from 80 to 90 Gm. and any number included between these two may be selected arbitrarily. The fats are then found by simple subtraction.

A quantitative order blank for diabetic menus may be secured from any standardized hospital, according to this blank the carbohydrates, proteins and fats are distributed for breakfast, dinner and supper. In writing the patient's menu it will be necessary to convert grams on the order blank to their equivalent measures on the menu. This is important, as these patients will not use scales properly.

The United States Department of Agriculture furnishes standard food tables with weights and their equivalent measurements. The patient's menu is simple and tells him what to eat for breakfast, dinner and supper in terms of standard portions such as cupfuls and tablespoonfuls. The patient is also given a food list of 3 per cent vegetables, 6 per cent vegetables, 10 per cent fruits and the various other groups. Each article of food in these different groups is accompanied by the portion that he may use. The amount of sugar present in the twenty-four hour specimens of urine serves as a guide to the patient's progress. For a quantitative test of the sugar in the urine 8 drops of urine is added to 1 drachm of Benedict's solution and heated for five minutes in a cup of boiling water. The formation of a green color means that less than 1 per cent of sugar is present. The formation of a yellow color indicates from 1 to 2 per cent, and a red color indicates 3 per cent or more of sugar. This test has proved of sufficient accuracy to be used as a substitute for the more technical methods.

#### Interpretation of Shadows in Urogram

DR OTTO J. WILHELM, St. Louis. The purpose of this presentation is to demonstrate that frequently perplexing conditions simulating calculi in the urinary tract are encountered and with meticulous examination they proved to be caused by other factors. Statistics show that but 5 per cent of renal calculi are demonstrable roentgenographically. It is not unusual to see shadows in the lower third of the ureter which are not caused by urinary calculi but by phleboliths or calcified extra-peritoneal lymph glands. In such cases the only means of accurate diagnosis is retrograde catheterization, the catheter coming in contact with the stone in its passage toward the pelvis or meeting with a complete block at the point where the calculus has lodged. Stones occurring in the pelvis or cortex of the kidney may remain there for years with no renal destruction or pain as long as sufficient drainage occurs to prevent backflow pressure. This "silent" type of stone is most frequently diagnosed by chance in roentgen examinations. Disease conditions of the gallbladder and appendix may simulate right-sided ureteral colic. Severe ureteral colic was formerly believed to be caused by traumatization of the ureteral wall by the descending calculus, but today urologists have proved that the pain is due to obstruction resulting in a dilated pelvis and

subsequent hydronephrosis. This fact is demonstrated by the relief afforded the patient when it is possible to manipulate a catheter past the blocked area and to drain the dilated pelvis.

An x-ray ureteral catheter is one's best ally in rendering a differential diagnosis between ureteral diseases of the stone, appendix and gallbladder, and phlebolith. One should always bear in mind that occasional intramural stones occur which will permit the catheter to pass without obstruction and for that reason are misleading. Shortly after the stone becomes lodged it traumatizes the ureteral mucosa and a stricture forms at this point with a dilatation of upper portion of the ureter. It is also possible for dilatation to occur below the point of stricture, apparently the result of an inflammatory loss of tone of the ureteral wall. The lower third of the ureter, especially the intramural portion, is an exception to the rule of dilatation. In these cases the ureter is more apt to become narrowed, owing to the increased amount of musculature and the edema of the surrounding tissues. On this type of case the cystoscope is a diagnostic aid and reveals a puffed, edematous ureteral orifice with marked ecchymosis of the vesical mucosa. Most ureteral calculi are found in the lower third of the ureter. They seldom remain long in the upper two thirds migrating rapidly toward the bladder.

#### The Blood Platelet Count in Post-operative Thrombosis

DRS R. B. H. GRADWOHL and SAMUEL J. HELLER, St. Louis. In a series of thirty-one cases, including twelve herniotomies, two cholecystectomies, fourteen pregnancies, six miscellaneous operations, one hemorrhoidectomy, five hysterectomies and two normal individuals, we found that a rise in blood platelets occurred in many patients following operations, particularly herniotomies. We could not draw any conclusions regarding the relationship between postoperative thrombosis and the blood platelet count owing to the fact that none of our cases studied presented a thrombosis during the course of the daily serial blood platelet counts. It seems probable, however, that there is a rise in blood platelets after certain operations. Whether an increase in blood platelets is the sole factor in thrombosis or a contributing factor could not be established.

#### Carcinoma of the Prostate

DR GEORGE H. EWELL, Madison, Wis. Carcinoma of the prostate accounts for a large percentage of the cases admitted to any active urologic service. In less than 5 per cent of the cases when first seen is the disease confined to the gland. The early tendency toward lymphatic and osseous metastasis makes early diagnosis very desirable. The fact that carcinoma may arise in any portion of the gland and not merely in the region beneath the posterior capsule only is of importance for early diagnosis. Carcinoma occurring in younger persons develops more rapidly and gives rise to earlier metastases than in older persons. Urinary symptoms usually lead the patient to consult his physician, pain in the pelvis and about the hips is the second most common symptom, the pain being due to lymphatic and perineural lymphatic metastases. Roentgen examination will reveal osseous metastases in a large percentage of the cases when they are first seen. Lymphatic and osseous metastases may exist without producing pain. Roentgen examination of the bones of the pelvis and the lower spine should be made as a routine in all suspected cases of carcinoma of the prostate. A careful examination of the prostate is the greatest resource in the diagnosis. However, the aspiration biopsy (technic of Ferguson) should be more widely employed. The results of treatment generally are still rather unsatisfactory. Interstitial irradiation, after the newly described method of Ferguson, and the radical operation of Young would probably be adequate for eradication of the lesion in many of the cases, provided they could be seen early. The public should be educated to annual physical examinations.

#### Chronic Prostatitis

DR DAVID B. STUTSMAN, St. Louis. In this clinical group I have considered only those cases which give definite subjective symptoms. These symptoms are more commonly pain and burning in the perineum or rectum, burning frequency or pain at intervals on urination, and various sex disorders. The latter symptom particularly has led this group frequently to

be classified as sexual neurasthenia. In such a patient the prostatic urethra from the verumontanum to the vesical orifice is intensely inflamed, usually with some fibrosis or contracture. It is largely from this source that the symptoms are derived, and while massage, dilation and instillation have proved beneficial, the relief in many instances has been unsatisfactory. Monopolar fulguration to the prostatic urethra, particularly around the verumontanum, has in many cases seemed to give more decided relief. In two cases showing this syndrome, the age of each being such that early hypertrophy might be present, resection of a moderate amount of tissue at the vesical orifice was done and some surface coagulation carried down into the prostatic urethra. The result was beneficial in each instance. Four other patients ranging in age from 32 to 40 were treated in the same manner. Two have shown complete relief and two relieved entirely except for some remaining sexual complaint. The comparative simplicity of the procedure with apparent results seems to warrant its trial in preference to the more radical drainage of prostate and vesicles.

#### Pararectal Fistula

DR W K MCINTIRE, St. Louis. The pararectal fistulas are of three types: (1) the blind internal pararectal, (2) complete pararectal, and (3) bilateral pararectal. The surgical treatment of a pararectal fistula differs from that of other fistulas, because of the anatomic relation of the main fistulous tract to the muscles controlling the anal outlet. If the surgical principle of laying open the tract from the external to the internal opening should be applied in this type of fistula in which the internal opening is above the level of the levator ani, not only would both sphincters and the muscular coats of the rectum be divided, but also the point of fusion of the levator ani with the external muscular coat of the rectum. This is of great importance, because incurable incontinence results. The incision should be through the tissues on the outer side of the main fistulous tract to the point where it passes through the wall of the rectum.

#### Management of Hyperthyroidism

DR E V MASTIN, St. Louis. The general term hyperthyroidism includes two separate and distinct diseases: exophthalmic goiter and toxic adenomas. The signs and symptoms of the two diseases may be so similar that a differential diagnosis is difficult. Hyperthyroidism plus dysthyroidism is present in the case of exophthalmic goiter, while uncomplicated hyperthyroidism, which can be reproduced experimentally by the administration of thyroid extract, accompanies the toxic adenoma. The cause of exophthalmic goiter is unknown.

Recurrence of hyperthyroidism is encountered in not more than 5 per cent and probably less than 3 per cent of all the patients on whom conservative double resection of the thyroid gland has been performed. Any assumption that inadequate surgery is the most frequent cause of recurrence disregards the fact that there may be recurrence of the stimulus that was the original cause of the disease. The nature of the latter is as yet a matter of speculation.

The cooperative management of patients with toxic goiter, whereby throughout the entire period of observation they are under the joint supervision of the internist and the surgeon, has greatly reduced the mortality.

The introduction of the use of compound solution of iodine in the preoperative preparation of patients with exophthalmic goiter has been the most momentous single advance in the surgical treatment of diseases of the thyroid since the advent of aseptic surgery. In cases of toxic adenoma, iodine seldom causes the marked improvement seen in cases of exophthalmic goiter. Compound solution of iodine will not cure exophthalmic goiter and its indiscriminate use is both dangerous and unscientific. It should be used only as a preoperative and postoperative adjunct and during hyperthyroid crises. These patients are put to bed as a routine procedure with an icebag over the precordium. They receive from 4,000 to 5,000 calories of food daily and from 3 to 4 quarts of fluid during twenty-four hours. It is advisable to administer a sedative and I prefer one of the barbitol preparations such as pentobarbital sodium or phenobarbital, given in doses of from  $\frac{1}{2}$  to  $1\frac{1}{2}$  grains (0.03 to 0.1 Gm) three times a day and at bedtime.

Usually 10 drops of compound solution of iodine is given in milk or cocoa three times a day between meals.

The glycogen reserve of patients with degenerative changes in the liver, as evidenced by the phenoltetrachlorophthalein retention test and those with diabetes mellitus, may be materially increased by preoperative preparations, in the first group, by the intravenous injection of 10 per cent dextrose in sodium chloride solution, in the second group by a diet high in calories and rich in carbohydrates, supplemented by adequate insulin to make possible the utilization of the food.

The essential technical features of the operation for goiter are (1) the removal of the excessive thyroid tissue with a minimal loss of blood and the least possible trauma to the contiguous structures, (2) the preservation of sufficient glandular tissue to maintain the basal metabolism within normal limits and (3) the maintenance of strict asepsis. Postoperatively, restlessness and pain are controlled by the rectal administration of  $1\frac{1}{2}$  grains (0.1 Gm) of pentobarbital sodium in 10 cc of saline solution every four hours and whenever it is necessary morphine from  $\frac{3}{16}$  to  $\frac{1}{4}$  grain (0.01 to 0.016 Gm) is given. The patients are kept very quiet for the first forty-eight hours, and a fluid intake of 3,000 cc is maintained by giving sufficient saline solution by hypodermoclysis and 10 per cent dextrose solution intravenously. Should a severe crisis develop, the patient is given increasing doses of compound solution of iodine in saline solution by hypodermoclysis or large doses of sodium iodide are given intravenously. A 10 to 20 per cent solution of dextrose is given by continuous venoclysis and nine or ten icebags are placed over the precordium and around the abdomen and the thighs. Blood transfusions are indicated at times. The oxygen tent is also a great aid.

#### Experimental Production of Fat Necrosis

DR M PINSON NEAL and MAX M ELLIS, PH D, Columbia. Langerhans in 1890 produced the first experimental necrosis of fat and expressed a belief that lipase was the causative factor. Since that time Opie, Wells and others have, as the result of experimentation, voiced the same assumption, but none of them have produced the proof. We were able to produce fat necrosis by the use of a concentrated lipase fraction obtained from the liver and pancreas of hogs and commercial pancreatin. In the literature there is an expression of general belief that lipase causes the splitting of fat after some other ingredient of the pancreas, possibly trypsin, has injured the cells. Since there was a question of trypsin being present in these animal tissue extractives, a source of material was sought that would be free of such substances. Extractives were prepared from the seeds of the common sunflower, unroasted Virginia peanuts, castor beans and Chinese soybeans. The lipase containing fractions obtained from these substances were potent in the production of fat necrosis and gave chemical and physical reactions for the enzyme lipase. These fractions were negative in the usual tests for trypsin and other proteolytic enzymes. The lipase-containing fractions have been used as intraperitoneal injections into 625 animals, including white rats, dogs, cats, turtles, fish, chickens, pigeons and water dogs. Fat necrosis has been produced in each of these except the water dog, only five animals of which type have been used. Experimental lesions of fat necrosis have been observed within six hours after injections of the substances. The condition is not fatal, though the factor which produces fat necrosis is often fatal.

#### Diagnosis of the Childhood Type of Tuberculosis

DR H L MANTZ, Kansas City. The childhood type of tuberculosis is that form of the disease characterized by primary single or multiple foci, with metastasis usually limited to the lymphatic system. The principal aids in the diagnosis are the history of exposure, the tuberculin reaction and the roentgen examination. Symptoms of infection may be present but they are not pathognomonic of tuberculosis and hence are of no diagnostic help. Physical signs are lacking except in a few cases. The Mantoux or intradermal test, with Koch's old tuberculin is the best method to use for the tuberculin test. If only one injection is used, 0.1 mg or 0.1 cc of 1:1,000 should be used. It is preferable to use graduated doses, beginning with 0.01 mg. It is unnecessary to use larger doses than the 1 mg. As a qualitative test the Mantoux

method is accurate. It can be used as a quantitative test in two ways. The doses may be varied from extremely small ones to those above a milligram, or the dose may be kept constant and the reactions measured. It is not yet safe to draw too definite a conclusion from the quantitative tests.

The chests of the patients in whom a positive reaction to tuberculin is noted should be subjected to roentgen examination. A large percentage will show no roentgenographic evidence of infection. Less than 5 per cent will show recent lesions. Interpretation of these films is not easy. Shadows cast by blood vessels are often diagnosed as calcium deposits. These are usually irregular in outline and density, while blood vessels are more homogeneous and have rounded borders. The classification of the patients has been done almost exclusively by roentgenograms. This practice sometimes leads to errors.

The laboratory has been neglected in the diagnosis of the childhood type of tuberculosis. Sputum may be recovered by gastric lavage and examined by the usual methods. Various blood examinations, such as erythrocyte sedimentation rates, leukocyte, lymphocyte and monocyte counts and ratios are used for diagnostic and prognostic purposes. Most of the tests are of value in the prognosis but are not to be relied on as diagnostic measures. Tuberculosis may simulate or be simulated by many diseases incident to childhood. Differential diagnosis is made by direct methods and by exclusion.

#### The Treatment of Childhood Tuberculosis

DR HARRY CALVIN BERGER, Kansas City. For decades the treatment of tuberculosis has been rest, food, fresh air and sunshine. Isolation is the one factor that has been added. Great strides have been made, however, in the technic of applying these measures, especially in the domains of orthopedic and thoracic surgery. The greatest advance has been in education and the development in both the profession and the lay public of a sane comprehension of the problem. In the treatment of tuberculosis in children, physicians must have the proper conception on the following points:

- 1 We are dealing with the individual in the springtime of life when growth is rapid, changes are swift and reaction differ from those encountered in later life.

- 2 We must differentiate clearly between the childhood type and the adult type, which is rare early in life.

- 3 We must fully realize that reinfection of an infected child is far more dangerous than the infection of a child not previously infected.

- 4 Diagnosis must not wait for the development of physical signs, it can be made early only by the skin test and the roentgenographic examination.

- 5 The history is of utmost importance.

- 6 Isolation from contacts wherever possible is the ideal.

In applying treatment, rest is of first importance. It should be applied with common sense with the child's cooperation and must be mental as well as physical. It may cause damage if overdone. The child's psychology must be considered. The air should be fresh and free from dust, fumes or soot. It should be plentiful and acquired without undue exposure or exertion. Sunlight and other forms of ultraviolet radiation may prove disadvantageous through overindulgence. The diet should be wholesome, balanced and rich in vitamins and proteins, it should never be forced. I administer reinforced cold liver oil and calcium with phosphorus (preferably a phytin) to my patients. I am not using Calmette's immunization.

#### Pneumothorax Treatment of Tuberculosis

DRS A C HENSKE and CHARLES W EHLERS, St. Louis. In all unilateral cases the following are the indications for pneumothorax treatment: (1) if there are constant rales to be heard over an area corresponding to two or more ribs or intercostal spaces accompanied by positive results from the sputum and roentgenographic examinations, (2) if the disease is acute, (3) if in spite of rest in bed the activity of the process persists or improvement is not satisfactory, (4) if the patient for any reason is unable to undergo prolonged hospitalization, (5) if there is repeated or severe hemoptysis or hemorrhage, (6) if there are cavities with copious secretions, (7) if certain complications, such as tuberculous laryngitis, should be present, (8) if there is massive atelectasis or mas-

sive fibrosis. In bilateral cases the same indications are employed, influenced somewhat by the condition in the contralateral lung. The literature shows that highly favorable results are obtained in a majority of statistics quoted. Notably among these are Bonzoni's series of 3,680 cases treated during the period between 1916 and 1925. Of this total, 25 per cent were described as cured, 27.1 per cent as improved and 31.2 per cent as having ended fatally. Of Matson's 423 cases, 32 per cent were described as clinically cured, 20 per cent as arrested, 16 per cent as unimproved and 22 per cent as having ended fatally. Our experience with pneumothorax treatment at the Mount St. Rose Hospital from 1929 to 1933 is similar to the quoted statistics as regards favorable results. Of 1,156 patients admitted during the period of five years, 185 (16.01 per cent) received artificial pneumothorax. This low percentage can be attributed to the fact that practically 96 per cent of our patients are in the second and third stages of the disease when they are admitted to the hospital.

The best results are obtained in the group in which the involvement is unilateral, and there are no adhesions to interfere, and in bilateral cases in which less than a third of the contralateral lung is involved. The immediate effects are compression and rest of the diseased lung. Resulting from this, in many instances, are closures of cavities, stimulation of fibrosis and reduction in the extent of the involved area. This treatment also has a marked effect on the temperature and sputum, in ninety-eight, or 53 per cent, of the patients the sputum, which had been positive, became negative and 123 patients, or 66 per cent, became afebrile.

#### Ocular Complications of Gonorrhea

DR CHARLES M SWAB, Omaha. Gonococcal infection of the ocular tissues is ordinarily a complication of gonorrhea of the genito-urinary tract. The treatment that has been found most effective in cases of ophthalmia neonatorum consists of: (1) compresses of iced boric acid solution for three minutes every two hours, (2) warm boric acid solution irrigations every two hours, (3) instillation of fresh 15 per cent mild silver protein every two hours, (4) application of sterile petrolatum on the lid edges every two hours. These measures were usually supplemented by foreign protein therapy. Fresh whole milk, boiled for four minutes, was injected into the gluteal region in doses of 0.5, 1 and 1.5 cc, respectively, on three successive days. Fourteen cases were cured without corneal involvement. Gonorrheal ophthalmia in adults is likely to yield corneal complications, the hazards to vision are greater than in ophthalmia neonatorum. Metastatic gonorrheal iridocyclitis may develop from a focus in the posterior urethra, it is characterized by a plastic exudate and a tendency to recur.

#### Nasal Allergy

DR ORVAL R WITHERS, Kansas City. Nasal allergy is the most frequent manifestation of the atopic state. It is an important consideration in all chronic conditions of the nose and sinuses. In most cases the symptoms are definite enough so that they may be classified as the seasonal or perennial type. The perennial type may be further subdivided into the intermittent and the continuous forms. In addition there is a large and somewhat confusing group composed of patients with mild nasal symptoms, which may or may not be complicated with infection. Foods, inhalants or bacteria may become the etiologic factors. Too much emphasis has been given to infection as an allergen in many instances because of the absence of skin reactions and the benefit to be derived from vaccine therapy. The characteristic symptoms are nasal obstruction, rhinorrhea, sneezing and itching of the nose, roof of the mouth and eyes. These symptoms will vary with the degree of sensitivity, the number of active allergens and the period of the sensitizations and the presence of secondary factors. The primary complications or those due to the allergic reactions, are (a) edematous and hypertrophic turbinates, (b) polypoid degeneration, (c) polyposis, and if allergy occurs early in life and of severe grade, (d) facial deformity. The secondary complications are recurrent sinusitis, headaches and asthma. It is of extreme importance to recognize the presence of allergy in cases showing obvious infections.

## Current Medical Literature

### AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to *THE JOURNAL* in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (\*) are abstracted below.

So-Called Breast Milk Intoxication T. Tanaka Yamaguchi Japan—p. 1286

**Vitamin A and Colds**—The Gardners found that supplementing the diet of school children with haliver oil or definitely enhancing it with vitamin A as found in foods decreased the incidence and severity of colds. Increased resistance was accompanied by a higher degree of general health, as was shown by an increase in weight.

**Chorea Treated with Phenylethylhydantoin and Typhoid Vaccine**—Monfort states that an analysis of the twenty-four cases of chorea treated with phenylethylhydantoin and typhoid-paratyphoid vaccine revealed that there were marked benefits from phenylethylhydantoin in some cases but that the average duration of the disease was twenty-four days in the majority of cases. In eight cases the condition was unimproved. In one case the drug caused death. The results of treatment with typhoid-paratyphoid vaccine showed that this form of therapy is not dangerous but that it produces chills during the febrile period. However, the duration of treatment with this preparation was shorter by eight days than that with phenylethylhydantoin, the average duration being about sixteen days. There were no recurrences of chorea in the twenty-three patients treated with typhoid-paratyphoid vaccine who were followed for one year and it was noted that carditis, the most dangerous sequel of chorea, did not occur in those treated with this preparation during this period. When typhoid paratyphoid vaccine was introduced, a definite change was observed in the acid base equilibrium. Invariably there was a low carbon dioxide content of the blood during the prolonged fever, with a low level for chlorides, a moderate increase of the calcium level and a decrease of the phosphorus level. In three cases the  $pH$  of the blood was slightly increased coincidentally with the lowering of the carbon dioxide content. Although there is

a lowering of the carbon dioxide volume per cent and of the chloride level, there is an increase in  $pH$ . The bases are not lost but are bound to the proteins, owing to the increase in  $pH$ . There is probably a sudden shift to alkalinity. Diminution of the blood pressure was also noted during the febrile period. The pulse pressure fell disproportionately more than the systolic pressure. Seventeen patients of the entire series treated with phenylethylhydantoin and typhoid-paratyphoid vaccine showed evidence of carditis on admission. Twenty-three patients had had their tonsils removed. Eight showed roentgenographic evidence of sinus and antral involvement. All the patients treated with typhoid-paratyphoid vaccine gave a positive Widal reaction in all dilutions during their stay in the hospital.

**Polyarteritis Nodosa**—Haining and Kimball are of the opinion that a specific filtrable virus with a selective affinity for the small and medium sized muscular type arteries of the body is probably the cause of polyarteritis nodosa. Any organ or combination of organs may be affected at any time in the course of the disease and the resulting clinical manifestations may be bizarre in the extreme. The visceral arteries are involved more frequently than those of the extremities, and the organs most commonly affected are the kidneys, heart, gastrointestinal tract, pancreas, muscles, peripheral nerves, liver, spleen and cerebrum. Pathologically the inflammatory changes are not confined to the adventitia and periarterial connective tissue, as originally supposed. All the vascular coats are eventually involved and the primary changes take place in the media. Destruction of the media may give rise to aneurysmal formation. Involvement of the intima with rupture of the elastic membrane may produce thrombosis. The process as a rule is progressive and in practically all reported cases there has been evidence of acute inflammatory changes superimposed on the chronic reparative efforts. However, Arkin has described a case of histologic healing and he believes that in rare instances the process may come to a complete standstill. Polyarteritis nodosa is seldom diagnosed or even suspected before necropsy, and even at necropsy there may be no gross indications of its presence. The internist should be familiar with the cardinal symptoms of the disease and its behavior. Then, when the commoner possibilities have been carefully ruled out in a patient with septic manifestations and varied symptomatology, polyarteritis nodosa should be given consideration. Carling and Hicks, and recently Schottstaedt have reported cases in which remission of symptoms seemed to follow the intravenous administration of arsenicals.

**Thrombopenic Purpura with Carcinoma of Stomach**—Lawrence and Mahoney present a case of thrombopenia as a complication of carcinoma of the stomach, in which there were

extensive bone marrow metastases. So far as the blood picture was concerned there was one observation that was unusual—the marked diminution in the number of the platelets. It would seem that the presence of large numbers of tumor cells in the bone marrow was the probable cause of the thrombopenia. However, studies of the bone marrow sections reveal an approximately normal number of morphologically normal megakaryocytes. Nevertheless, the presence of these megakaryocytes does not prove that these cells were functionally normal. Increased peripheral destruction or loss of platelets cannot be excluded. The question arises as to the relation of the thrombopenia to the hemorrhagic diathesis. The authors believe that the connection is probably close, although it would be impossible to say that the bleeding phenomena were not dependent, in part, on changes that may have occurred in the permeability of the capillary walls. The presence of large numbers of early cells of the myeloid series and of numerous nucleated red blood cells is not unusual. It is unusual to find large numbers of nucleated red blood cells and many early myeloid cells in idiopathic thrombopenic purpura, although they may be found after recent massive hemorrhage. The value of studies of the sternal marrow in such persons cannot be emphasized too strongly. The authors believe that, had they been able to obtain a sternal marrow biopsy from this patient during life a positive diagnosis could have been made. This procedure was planned, but the sudden death of the patient prevented it.

**Sarcosporidia in Myocardium of Premature Infant**—Hertig observed a sarcosporidial infection in the myocardium of a premature infant in which the sarcosporidial cysts were in the early stage of development. Even in experimental studies it is uncommon to find sarcocysts with fewer than eight spores, although moderate numbers of the forms studied here were of this type. The method of infection is unknown. However, since the infant was 26 days of age at death, the infection could have been contracted shortly after birth, because the stage of development coincides with that seen in animals from twenty-six to twenty-nine days after ingestion of the infective spores. Theobald Smith and Scott state that intra-uterine infections do not occur in the lower animals, although this method cannot be ruled out in this case. Since mouse feces are known to be infective and since indigenous mouse infections may be common, this might have been a source of infection.

**Hematoporphyrin as Therapeutic Agent in the Psychoses**—Strecker and his co-workers studied the responses of thirty-seven patients to the administration of hematoporphyrin. Twenty-three patients with manic-depressive reactions were treated during the depressed phase with intramuscular and oral administration of hematoporphyrin hydrochloride for an average period of from fifty to sixty days. Of this number five showed marked sustained improvement, six showed moderate sustained

improvement and six were generally benefited, but the course of the psychosis did not seem to be positively affected. Six gave no favorable response. Seventeen of the twenty-three patients may be said to have been definitely helped by the treatment. Four of eight patients suffering from involutional melancholia showed marked improvement, which has been maintained after the treatment was terminated. One was moderately improved and has maintained this gain. Two were generally better during and after treatment but have not made complete recoveries. Only one failed to respond favorably. Of six schizophrenic patients, one made substantial physical gains, has remained generally better and has adjusted his life at a considerably lower level but is working steadily. Definite stimulation and animation were evident in all the schizophrenic patients treated, but in five of these the reaction was not of constructive nature. These five subsided into passive states after the treatment was discontinued. The authors conclude that when hematoporphyrin is administered to psychotic patients the substance in some way increases the available energy of the person. Whatever the physiologic action, the actual somatic and psychic benefits seem to be derived from its administration. The intramuscular injections consisted of 1 cc of solution (2 mg of hematoporphyrin hydrochloride) every other day for twenty days and then after a rest period of from five to seven days a second course of 2 cc of solution (4 mg of hematoporphyrin hydrochloride) every other day for a period of twenty days. In a number of cases a third series of 2 cc injections was given. Oral doses were begun at 10 drops of solution (3 mg of hematoporphyrin hydrochloride) three times a day, before meals, during the first series of intramuscular injections, increasing to from 15 to 30 drops (5 to 10 mg of hematoporphyrin hydrochloride) three times a day, before meals, during the second and third series.

**Malignant Hypertension. Histologic Changes in Kidneys**—Cain found diffuse changes involving glomeruli, tubules, arterioles, arteries and interstitial tissue in a group of cases of malignant hypertension. The most prominent changes occurred in the arterioles, they consisted in extreme narrowing of the lumen, apparent increase in the numbers of endothelial cells, subendothelial fatty and hyaline degeneration, apparent thickening of the tunica media and an increased amount of connective tissue chiefly in the tunica adventitia. The ratios of the wall to the lumen of the renal arterioles were markedly reduced. The kidneys were not markedly or uniformly decreased in size.

**Effect of Arteriosclerosis on Area of Histamine Flares**—Ernstene and Snyder measured the area of the flare produced by injecting 0.02 cc of a 1:2,000 solution of histamine dihydrochloride into the skin of the midforearm in normal persons, in patients having arteriosclerosis and normal blood pressure and

in patients having benign essential hypertension, hypertension of the intermediate grade and malignant hypertension. The average area of the flare in thirty normal persons was 31 sq cm, and the smallest flare recorded had an area of 18 sq cm. A distinct tendency toward flares of diminished size was observed in the patients having arteriosclerosis and normal blood pressure. In eleven patients who had slight or moderate degrees of arteriosclerosis the average area of the flare was 22 sq cm, while the average area in fourteen patients having advanced arteriosclerosis was 18 sq cm. Three patients of the first group and nine of the second had flares of smaller size than the smallest obtained in a normal person. The area of the flare was within the limits of normal in twenty-one patients having benign essential hypertension and the average area for the group was 29 sq cm. The average area of the flare in eleven patients having hypertension of the intermediate grade was reduced to 20 sq cm. Four of these patients had smaller flares than the smallest observed in a normal person. In eleven of sixteen patients who had malignant hypertension the area of the flare was less than the smallest recorded in a normal person, while in only three did it exceed 24 sq cm. The average area for the group was 16 sq cm, approximately one half the average in normal persons. The results indicate that observations on the area of the histamine flare should prove a useful adjunct in distinguishing the intermediate and malignant types of hypertension from the benign form.

**Periosteal Ossification in Myelogenous Leukemia**—Ehrlich and Forer report a case of "acute" myeloid leukemia which presented the picture of acute rheumatic fever during an aleukemic phase and which at necropsy presented the anatomic evidence of both diseases. The occurrence of periosteal changes in the left humerus at the beginning of the clinical course was found at necropsy to have occurred on the basis of repeated subperiosteal leukemic infiltrations with secondary ossification in layers. The authors state that a review of the literature of the changes in the bone in leukemia and the study of their case result in the inclusion of leukemia in the differential diagnosis of periosteal elevation and ossification.

**Etiology of Epilepsy, Especially in Twins**—Rosanoff and his associates present 107 cases of twins in which at least one of the twins had epilepsy. The distribution of epilepsy and other neuropsychiatric conditions found among the other twins of the pairs is as follows: (1) in monozygotic twins, epilepsy, twelve; deteriorating psychosis, and tumor of the spinal cord, one each, normal, nine (39.1 per cent); (2) in dizygotic twins, epilepsy, nine; mental deficiency, six; mental deficiency with psychosis, mental deficiency with behavior difficulty, deteriorating psychosis, behavior difficulty and dementia paralytica, one each, normal, sixty-four (76.2 per cent). Hereditary factors undoubtedly exist in the etiology of epilepsy, as is indicated by the comparison of monozygotic and dizygotic twins. Epilepsy, especially that existing from birth or from an early age is closely related by both individual and familial association to certain cases of mental deficiency and Little's disease. The borderland of epilepsy is, moreover, replete with other conditions, particularly psychotic disease, behavior problems, jacksonian fits, left-handedness and possibly certain conditions often seen among school children, namely, stammering, other disorders of speech and cases of 'nonreaders'

and constitutionally poor spellers. Evidence has accumulated in the past fifteen or twenty years to the effect that epilepsy, traditionally considered a neurosis, functional in nature and "idiopathic" in etiology, is rather a decerebration syndrome, definitely organic. Its relationship to other decerebration syndromes, such as mental deficiency, Little's disease and the other conditions, suggests a common factor of etiology, namely, trauma at birth. There seem to be two factors involved: trauma at birth and vulnerability. The severity of trauma at birth is determined by conditions causing dystocia, primiparity, premature rupture of the membranes, abnormal presentations and contracted pelvis. The degree of vulnerability also varies according to certain conditions: a hereditary factor, a sex factor, premature birth or an underweight condition at birth, and the handicapping conditions of multiple pregnancy. It has been shown statistically that epilepsy, mental deficiency and some other clinical types of decerebration occur with relatively greater frequency among the first-born—a fact that points to trauma at birth. In connection with postnatal trauma, age seems to be an important factor in the etiology of epilepsy. Whereas trauma to the head sustained in infancy, childhood or adolescence frequently causes epilepsy, in later life it does so in but a small proportion of cases. The epileptic syndrome in traumatic cases is determined not by the severity or extent of the original injury to the brain but by its localization or by the inflammatory reaction with progressive tissue change that follows it, or by both. Chronic and deteriorating psychotic disease is frequently associated with epilepsy both in individual cases and in familial groups. In individual cases there is not necessarily a correspondence in severity between the epileptic and the psychotic manifestations. These facts, together with evidence yielded by some cases among twins, indicate that some chronic and deteriorating psychoses which are usually counted as dementia praecox in the statistics of state hospitals are really but a special clinical type of decerebration, based on an etiology similar in many cases to that of epilepsy, mental deficiency and Little's disease. The occurrence of epileptic syndromes in connection with nontraumatic conditions is not inconsistent with the decerebration theory of epilepsy. Decerebrating effects can be produced by a tumor of the brain, neurosyphilis and cerebral arteriosclerosis or, even in the absence of brain lesion, by toxic, autotoxic, infectious or circulatory factors.

**Encephalographic Studies in Manic-Depressive Psychosis**—Moore and his associates made an encephalographic study of thirty eight cases of manic depressive psychosis in various stages of the manic depressive cycle. They found that the cerebrospinal fluid pressure, in terms of millimeters of mercury, have in the majority of cases been too normal or higher, indicating the presence of the factor of chronic increased intracranial pressure. The quantity of cerebrospinal fluid removed in the majority of cases has indicated varying degrees of cortical atrophy and enlargement of the ventricular system and cisterns. No definite cerebral pattern is obtained in a sufficient number of cases to be characteristic. The encephalographic pathologic condition is manifested in the following ways: (1) cortical atrophy of varying intensity, (2) enlargement of the ventricular system, (3) asymmetry of the lateral ventricles, (4) absence of cortical air markings, (5) enlargement of the cisterns, (6) island of Reil atrophy, (7) enlargement of the sulcus callosi and sulcus cinguli, (8) increased interhemispheric air and (9) cerebellar atrophy. None of the encephalograms showed a normal cerebral pattern.

**Sclerotic Atrophy of the Cerebellum**—Hassin reports two cases of sclerotic atrophy of the cerebellum from the study of which he concludes that atrophy of the cerebellum may be an acquired morbid condition and in cases of long standing may result in sclerosis of parts of the cerebellum. The lateral lobes especially the upper semilunar and the quadrilateral may alone be involved, or they may be affected together with the vermis. Histologically the condition somewhat resembles that occurring in any other terminal degenerative state when the nerve tissue is replaced by a glial tissue scar. The cerebellar atrophy resulting from sclerosis has its homologue in the cerebral atrophy and sclerosis known as Pick's disease and pos-

sesses no specific histologic features. The striking pathologic feature is calcification of the Purkinje cells in the areas that are undergoing atrophy. The clinical features cannot be considered specific, and, as they may be absent altogether, a pathologic condition of this sort remains undiagnosed.

**Changes in the Bone in Hodgkin's Granuloma**—Craver and Copeland studied histologically 172 patients having Hodgkin's granuloma. Twenty-seven patients were found to have involvement of the bone. The bones most frequently involved were those of the spine and the pelvis. Pathologic fracture was rare, but collapse of the vertebrae was frequent. The two types of osseous changes were osteoplastic and osteolytic. A combination of the two was seen in many cases. Osseous involvement may be assumed to arise from the marrow foci of Hodgkin's granuloma or from the contiguous diseased lymph nodes from which direct infiltration into bone occurs. The intervertebral disks were involved rarely. No relationship between the structure of the lymph nodes and the type of osseous change could be demonstrated. The authors found Heublen's method of prolonged continuous low intensity irradiation of the entire body to be a valuable part of the treatment in a number of cases. The gross lesions of the bones may be treated to good advantage either by single large suberythema doses or by fractional doses of high voltage roentgen rays. Relief from pain is often prompt and reparative processes may be demonstrated in some cases. In the terminal stages they do not attempt routine irradiation of all the bones, although it is well known that the marrow is usually diffusely involved, as in such cases a severe degree of anemia and sometimes leukopenia already exists and would only be aggravated by irradiation.

**Diathermy and Regeneration of Bone**—Weinberg and Ward endeavored to determine whether there is an actual rise in temperature in bone when an extremity of an experimental animal is submitted to treatments with diathermy, if there is a rise in the temperature of bone, whether this results in any demonstrable physiologic effect on bone in normal laboratory animals, and whether this physiologic effect, if present, hastens repair processes following injury to the bone. During post-operative treatment with diathermy, bleeding from the open wound was found to be due to the treatment. There was a free flow of blood shortly after the turning on of the current, but the bleeding stopped as soon as the heat was discontinued and the leg allowed to cool a little. As soon as hot electrodes touched the leg of the animal a rapid rise in temperature occurred in both the muscle and the bone, demonstrating that with such a small part of the body as the dog's forelegs external heat will also raise the temperature of the bone. This seems to indicate that in these animals, at least, therapeutic effects may be obtained by the external application of hot objects. The rise in temperature of the muscles and that of

the bones are nearly parallel. The temperature of the muscles rises a little faster at first, to be overtaken late by the temperature of the bones, which, near the end of the experiment, again falls. In one week microscopic changes in the treated leg, in which the hole was filled with vascularized connective tissue, a few degenerated red blood cells and a small amount of bone dust, showed formation of new bone arising from the cut edges of the endosteum. The endosteum in the neighborhood of the hole showed a marked proliferation of osteoid tissue extending down into the marrow cavity, and the marrow cavity near the hole was filled with young fibrous connective tissue, which was highly vascularized. In two weeks the treated leg showed marked formation of new bone arising from the periosteum, the endosteum and the cut edges of the compacta. In three weeks there was a decided advance in the periosteal and endosteal formation of new bone, and in four weeks the treated leg revealed marked new periosteal bone. In four weeks in the control leg there was little or no periosteal new bone, and the hole was filled with a lamellar type of bone, so that it was not yet healed.

### Causes of Death Following Acute Portal Obstruction

—In an effort to explain the cause of death following ligation of the portal vein, Elman and Cole resorted to many different types of experiments. It seems clear to them that the rapid death which so regularly follows total occlusion of the portal vein is due to circulatory failure, because of extensive loss of blood from the general circulation into the trapped splanchnic area. No evidence of the production or absorption of a toxic substance (by guinea pigs and white mice) was found. The evidence in favor of the purely physical factor was uniform and consistent. The increase in weight of the splanchnic area following occlusion of the portal vein was great enough, on the basis of the amount of entrapped blood it contained, to have caused death from shock alone. The fall in blood pressure was similar to that noted after an extensive hemorrhage except that the pressure was sustained at a low level until death. The behavior and appearance of the animal after ligation of the portal vein were similar to those seen after marked loss of blood from hemorrhage. Attempts to raise the blood pressure and prolong life by transfusions of blood were successful, and it was possible to postpone death for more than six hours. It was possible to prolong life and prevent the characteristic fall of blood pressure following occlusion of the portal vein by ligating the aorta above the celiac axis, which effectively stopped blood from entering the splanchnic area. These animals lived only a few hours, but they lived as long as animals with ligation of the aorta alone. The results of the experiment were the same if, in addition, several hundred cubic centimeters of blood was injected into the mesenteric arteries to produce the cyanosis and congestion ordinarily seen after ligation of the portal vein. Death following ligation of the portal vein is probably hastened by the fact that ligation at the same time prevents the gastrointestinal tract from aiding in the loss of fluid. When a low blood pressure is maintained too long it can never be corrected, no matter how much blood is transfused. The effect may be due to changes produced in the nerve cells. It is likely that too low a pressure slows the metabolic exchange and causes irreparable alteration in the central nervous system. On the other hand, the defect caused by a low pressure may be due to increased capillary permeability.

**Early Recognition and Treatment of Malignant Changes of the Skin**—Lingenfelter and Ambler state that there is no one method in the treatment of malignant conditions of the skin that can be used successfully to the exclusion of all others. They advise the use of the scalpel, the high fre

quency cutting current, electrodesiccation, electrocoagulation, radium and x-rays, or a combination of two or more methods according to the case. The choice of therapy to be employed is dependent on various factors. Early basal cell and squamous cell carcinomas are often eliminated with comparative ease by the use of radium or x-rays. However they believe that in early lesions of both types a combination of some electrosurgical or surgical procedure combined with radiation is the safer method. To delay radical removal of such growths until radiation alone has been tried frequently changes the lesion from a minor one to one the complete removal of which may produce marked deformity. Except as a palliative measure, surface irradiation alone is rarely indicated for the more advanced or recurrent lesions. A combination with one or more of the surgical procedures is usually required. The authors give a brief description of the improved radium technic of Regand and Cade and its advantage over surgery in the treatment of intra oral carcinoma.

**Ephedrine in Narcolepsy**—Johnson reports a case of narcolepsy which confirms the results obtained by Doyle and Daniels in the treatment of narcolepsy with ephedrine. The patient, a nursing mother, was put on a blood building diet and given hydrochloric acid and pepsin, and also liver extract. Ephedrine hydrochloride was begun in a dosage of 0.0325 Gm at 8 a m, 12 m and 4 p m. The patient had immediate relief from the sleeping attacks. Five days later she reported complete relief. The medicine seemed to have no ill effects on either the mother or the baby. Seven months later the patient was still doing well, having no recurrence of symptoms as long as she keeps taking ephedrine. The patient has noticed that if she goes out in the evening the dosage is not quite sufficient therefore she is given an additional half grain on these occasions.

**Aseptic Uretero-Intestinal Anastomosis**—Higgins presents a technic for simultaneous bilateral transplantation of the ureters into the rectum in which the normal course of the urine and the continuity of the ureter are preserved until after the formation of a new channel between the ureter and the rectosigmoid. The procedure is attended by no interruption of kidney function during the establishment of the new channel between the ureter and the intestine. The mortality in experimental animals has been practically negligible. The almost complete absence of peritonitis and acute renal infection has been remarkable. The immediate results in the author's eight clinical cases are gratifying but he believes that insufficient time has elapsed to warrant any statement as to the ultimate results. The technic is as follows. A low median incision is

made with the subject in a moderate Trendelenburg position. After the peritoneal cavity has been opened the intestine is displaced from the pelvis and held away from the operative field by moist tapes. The posterior parietal peritonum is incised over the ureter at the usual site for transplantation and then freed from its bed by sharp dissection thus isolating the ureter for approximately 8 cm. The point of transplantation into the rectosigmoid is selected and an incision 6.5 cm in length is made along one of the longitudinal bands through the serous and muscular layers to the mucous membrane of the intestine. Lateral separation of the serous and muscular layers provides a trough, which is to be occupied by the transplanted ureter. The intestine is replaced in its normal position, the ureter is grasped at points adjacent to the trough in the intestine and placed in the trough in the intestine. A silk suture is passed about 1 cm from the lower angle of the incision in the intestine through the wall of the ureter, which is in contact with the intestinal mucous membrane. This suture, preferably of the mattress type passes into the lumen of the ureter itself and is passed through the mucous membrane of the intestine and tied tightly. The new channel should be produced near the distal end of the incision through the serous and muscular layers. To avoid contamination, the suture is always passed first through the ureteral wall and then through the mucous membrane of the intestine. The muscular and serous layers are reapproximated with interrupted silk sutures over the ureter. The ureter is thus incorporated in the intestinal wall for 3 to 4 cm and the valve principle is allowed to function. Following the reapproximation of the serous and muscular layers over the ureter the cut edge of the peritoneum (postparietal) is stitched over the site of the incision in the intestine. After the new channel has been formed and intravenous urography demonstrates that it is functioning, cystectomy is performed.

**Subcutaneous Vasoligation**—Short describes a method of subcutaneous vasoligation that can be carried out quickly without assistance and one that requires no after-care. Although the procedure can be performed with an ordinary three-eighths circle cutting needle, the operation is greatly facilitated by the use of a similarly curved cutting needle carrying the eye 0.5 cm from the proximal end which also has a cutting point. In addition to a needle ligature and needle holder, a narrow-bladed knife scissors and a hypodermic syringe containing a local anesthetic are required. The scrotum and adjacent parts are prepared by shaving, cleansing and the application of an antiseptic, and the penis is held upward against the abdomen with adhesive tape. The spermatic cord is grasped at a convenient point in the upper part of the scrotum and pulled forward. This facilitates the invagination of the left index finger, palmar surface forward behind the entire cord at the same level. As the right hand releases the cord, allowing it to slip slowly backward, the vas is identified between the fingers by palpation and isolated over the left index finger below the middle of the distal phalanx, while the remainder of the cord is retracted outward by the left thumb and maintained in that position. A small area of skin 1 cm medial to the isolated vas is injected with procaine and a linear incision or nick from 3 to 4 mm in length is made through the skin. This is most readily accomplished by transfixion with a narrow blade, such as a cataract knife. Capillary oozing may be disregarded. The needle armed with silk is then introduced through this opening and guided beneath the vas by the tactile sensation of the left index finger supporting it, and pushed through the skin beyond the vas but medial to the bulk of the cord still reflected outward by the thumb. At this time the accuracy of the placement of the needle can be verified by palpation of the overlying vas against it. The needle is grasped at its point of emergence and advanced farther until the proximal end has cleared the vas. The needle is then reversed over the vas, pushed back into the original opening in the skin and drawn through. The ligature is tied tightly the ends are cut short and on its release the knot usually clears the skin which falls together over it. A dab of cotton is applied with collodion and no further attention is required. The wound heals by first intention leaving no perceptible scar while the vas tends in time to resume its usual position.

**Perforations of the Labia Minora**—Stude cites three cases of perforation of the labia minora. The first case was considered to be of syphilitic origin in spite of a negative Wassermann reaction, since it presented a combination of both active and healed lesions. Other facts that pointed to syphilis as the etiologic factor were the patient's general physical status, the observations revealed by microscopic study of tissue sections and the extremely large number of perforations, which practically ruled out traumatism as a cause. In the second case the squamous cell carcinoma was evidently a secondary development, since the margins of the perforation were perfectly smooth and intact throughout the greater part of their extent. The evidence indicated the perforation to be the result of a chronic inflammatory ulceration either syphilitic or tuberculous in nature, most probably the former. In the third case either traumatism during labor or congenital malformation was to blame, although it is impossible to state which of these two causes was responsible. If the perforation is healed without ulceration, no local treatment is indicated. A Wassermann test, however, should be done and the patient examined for tuberculosis. In chronic ulceration, a specimen of tissue should be taken from the ulcerated area and studied microscopically. If this is not malignant, no special local treatment is necessary when the condition is proved to be of syphilitic origin. Tuberculous ulcers should be excised and chancroidal ulcers should be cauterized. Local cauterization combined with the intravenous injection of antimony and potassium tartrate has proved best in the treatment of inguinal granuloma. When cancer is present, complete vulvectomy and the removal of the inguinal and femoral lymph nodes are to be done if the patient's condition permits, otherwise resort may be had to the use of roentgen therapy.

**Effect of Dinitrophenol on Metabolism in Schizophrenia**—In order to study the effect of raising the low basal metabolic rate, which is consistently found in schizophrenic patients, by the use of alpha-dinitrophenol, Looney and Hoskins administered the drug to ten patients in doses of from 3 to 4 mg per kilogram of weight for a period of forty-nine days. Each week analyses were made of the blood for complete nitrogen partitions, sugar, cholesterol, lactic acid, glutathione, carbon dioxide, oxygen and  $p_{H}$ . Nitrogen partitions

were made on urine as well as routine qualitative analyses. It was found that there was an increase in the basal metabolic rate of approximately 50 per cent without any concurrent change in blood pressure and pulse rate or temperature. At first there was a gradual increase in the nonprotein nitrogen, urea nitrogen and uric acid nitrogen, which again receded to normal as the treatment continued. Blood cholesterol and lactic acid showed considerable variation but no consistent trend. Patients lost from  $4\frac{1}{2}$  to  $6\frac{1}{2}$  pounds (2 to 3 Kg) in weight, but no deleterious effects were noted.

**Pitressin Test in Epilepsy**—Jacobsen believes that retention of fluid in the body tends to induce seizures and uses this fact as the basis of a test for epilepsy. By means of the pitressin test a child having seizures can be caused promptly to have a typical seizure, provided it is a case of epilepsy. The procedure is to give fluids to the point of establishing a positive water balance, and, when water has been retained to the extent of causing an increase of body weight of from 3 to 6 per cent or more, a convulsion will result. Under ordinary conditions, output will keep pace with intake and no retention will result. But by making use of the antidiuretic effect of pitressin a positive water balance is readily induced. In itself pitressin cannot produce a convulsion in the normal or in the epileptic subject. The application of the test consists in giving 300 cc of water every two hours and an injection of pitressin every four hours, until a positive water balance is established. The dose is 0.2, 0.3, 0.4 cc, and thereafter 0.5 cc doses until a seizure occurs or until about eight or ten doses have been given. If a seizure occurs, no nourishment or fluids are to be given except 1 cc of cream per pound of body weight every four hours. This seems to be the most effective way to eliminate further seizures. The author has used the test in about forty cases and thus far has found it reliable. The only cases in which it was of no help were those few in which no positive water balance could be established, even with pitressin, and therefore the negative results could not rule out epilepsy. Two children became nauseated so that the test had to be discontinued. In the large number of cases in which the type of seizure is indeterminate, this test proves a valuable aid to diagnosis.

**Silicosis Among Granite Quarriers**—Bloomfield and Dreessen present a study of the effects of the inhalation of granite dust generated in granite quarrying. A clinico-roentgenographic study of sixty-three granite quarriers was made, in addition to determinations of the occupational dust exposure. The dust determinations showed that 38 per cent of the workers (drillers) were exposed to many times the amount of dust considered safe at the present time. The clinical observations disclosed that drillers were the only persons showing pathologic lung changes. Half of these workers with an exposure of from five to nineteen years had silicosis, and four of the five men with more than twenty years of such occupation showed this condition. The study suggests that quarry drillers may experience as high a death rate from pulmonary tuberculosis as do other pneumatic tool workers in granite cutting sheds. The authors cite methods for the elimination of dust in quarry operations.

**Referred Abdominal Symptoms in Pulmonary Tuberculosis**—Brown presents a study of 400 patients having pulmonary tuberculosis in whom intestinal tuberculosis had been excluded. Failure to exclude the presence of intestinal tuberculosis renders previous studies of referred abdominal symptoms of little value. The chronicity of pulmonary tuberculosis

and the method of its treatment increase the likelihood of the occurrence of referred abdominal symptoms during its course. In the majority of patients in early stages under proper treatment the referred abdominal symptoms are of little moment. In the advanced stages of the disease the majority of the patients have intestinal tuberculosis and the symptoms are to be attributed in part to them. This complication can exist without any abdominal symptoms whatever. The abdominal symptoms referable to the surgical treatment of pulmonary tuberculosis (artificial pneumothorax, phrenic operation, thoracoplasty) are usually slight, though they may be pronounced and troublesome. Referred abdominal symptoms are more common during acute types or acute exacerbations of the pulmonary tuberculosis. The symptoms referable probably to the intestinal tuberculosis are often more pronounced and more persistent than the referred symptoms. The cause or causes of the referred abdominal symptoms in pulmonary tuberculosis have not yet been definitely determined. It is likely that a number of different causes act to bring about these symptoms. Cooperation between the gastro-enterologist, the roentgenographer and the tuberculosis specialist will eventually solve the problem.

**Pituitarism in Neurologic Practice**—Tucker states that the clinical signs and roentgen observations of his 500 cases of pituitary disorders concomitant with neurologic disorders coincided in the majority of instances. The basal metabolic rate showed a decided tendency to be decreased in hypopituitarism. There were an equal number on each side of the zero point in hyperpituitarism. The influence of the other endocrine glands and the difference in the function of the two lobes of the hypophysis must be considered, as the oversecretion of the anterior lobe is more frequent than that of the posterior lobe and is believed to have little or nothing to do with metabolism. Blood sugar estimations in the hypopituitary cases did not conform in percentage to the "low sugar, high tolerance" ratio that is generally accepted. The sugar level in hyperpituitarism showed a definite tendency to be increased above the normal. No reduction can be drawn from the blood calcium estimation. Attention, however, is called toward decreased calcium content in hypopituitarism and hyperpituitarism. Twenty-one per cent of hypopituitary cases, 12 per cent of conduct disturbance and 23 per cent of bitemporal headaches originated in adolescence. Evidence of disorder in other endocrine glands is noticeably present in more than 25 per cent of the cases analyzed. Closer observation of clinical evidence and research in the biochemical field as an aid in differential diagnosis of endocrine disorders is desired.

\*Influenza with Especial Reference to the Complications and Sequelae. Bacteriology of Influenzal Pneumonia. Pathology. Epidemiologic Data. Prevention and Treatment. Part II. D. Thomson and R. Thomson.—p. 641.

**Review of Literature on Influenza**—The monograph (two volumes) of the Thomsons on influenza consists of forty-six chapters, with an addendum references to the literature and a subject and author index. In their summary under treatment of influenza they state that good results have been claimed by methods which directly stimulate a leukopoiesis. Willmore and Gardner-Medwin found that injection of sodium nucleinate and the giving of large doses of alkali at the same time to neutralize the toxins in the system were beneficial. Other observers claim good results by inducing fixation abscesses. Petranyi claims successful results in the treatment of babies and young children with large doses of amidopyrine. It must be concluded, however, that there is no definite specific remedy for influenza. In consequence treatment has to be directed to the clinical symptoms and condition of the patient and to the relief of any prominent symptoms and complications. The most important measures in the authors' opinion in the treatment of influenza are as follows: 1. The patient should go to bed at once, however mild the case, and remain in bed until the temperature has been normal for two days. 2. The intestine should be cleared out daily or twice daily as an attack tends to induce constipation. 3. The patient should be kept warm and encouraged to perspire by means of hot bottles and hot drinks. A powder of ipecac and opium at night is excellent. 4. Stimulants should be given, not at the beginning but toward the end of the attack, and more especially during convalescence.

**Nonunion of Fractures**—Jones states that nonunion of fractures is almost always avoidable and is a complication entirely within the control of the surgeon. Many physiologic and biochemical factors may be concerned in the rate of union of fractures, but the only factor that is of practical importance in determining nonunion is inadequate immobilization. Immobilization may be inadequate in that the fracture is allowed movement within the splints or plaster rotatory movement is especially inimical to union and immobilization is not continued for a sufficiently long period. There can be no fixed period of immobilization for any fracture; the average duration of immobility may be exceeded in occasional cases by many months. Hyperemic decalcification and ischemic recalcification of bone must be accepted as pathologic facts. The initial traumatic hyperemia mobilizes calcium salts from the bone ends but rapidly subsides and allows recalcification of the young

connective tissue to form callus. With final repair and fibrosis the callus consolidates by increased calcification. If the hyperemia is perpetuated by the trauma of movement there is excessive decalcification—a crack fracture becomes a gap fracture. This is the first stage of nonunion. In the final phase of ischemic fibrosis the surfaces of the fragments undergo sclerosis, this is the second stage of nonunion. The two stages of nonunion are distinguishable roentgenographically. The first is cured by immobilization. In the second, preliminary revascularization is necessary by a drilling or grafting operation. The infected compound fracture is pathologically similar to the simple fracture, except that the initial stage of decalcification is prolonged. If it is immobilized the fracture will usually unite. An old infected fracture that has not been immobilized is in the first stage of nonunion so long as the infection is active but passes into the second stage of nonunion after quiescence of the infection. In the first stage, sequestrectomy without "scraping" followed by immobilization, determines union. In the second stage a revascularizing operation is necessary. Even if the operation is followed by a flare of infection, the fracture still unites if it is immobilized.

**Infections of the Urinary Tract**—Hammond states that it is only when a ureter is completely obstructed or when an abscess is developing in the substance of the kidney that an infection can exist without its presence being revealed by pus or bacteria in the urine. When pus is present the urine may be turbid but turbidity may be due to phosphates. When bacteria are present in large numbers the urine may present an opalescent appearance and a shimmering appearance when held up to the light. Having proved that some infection is present, one must find from what part of the urinary tract it comes and what is the pathologic lesion giving rise to it. When an inflammation is limited to the anterior urethra, the pus and bacteria are swept out by the first portion of urine. This is the basis of the two glass test. The author believes this to be somewhat crude and proposes the following method. The meatus is first examined to see whether it is inflamed; the finger is then pressed along the floor of the urethra, and any discharge is collected on a slide. The anterior urethra is then washed out with physiologic solution of sodium chloride, flowing from a container placed two feet above the level of the patient. The wash-out contains the secretion of the anterior urethra and is collected in the first glass. About 2 ounces of urine is then passed into the second glass; this holds the contents of the posterior urethra. About 2 ounces of urine is passed into the third glass; this shows the condition present in the bladder. A finger is then inserted into the rectum, the prostate is massaged and 2 ounces of urine is passed into a fourth glass. The turbidity of the contents of the glasses is noted and each is examined for pus. If the second, third and fourth glasses contain pus, there is some cystitis, but if the second contains more there is a posterior urethritis. If the fourth contains more, there is associated prostatitis. In the prevention of infection methenamine should be given both before and after operations and during the last few months of pregnancy and during the puerperium. In the large pyonephrosis in women in whom nephrectomy has to be performed, the history of lumbar pain often dates back to a previous pregnancy. It is probable that the dilatation of the pelvis persists and the kidney may be gradually converted into a pyonephrosis. Consequently when a pyelitis has arisen during pregnancy three months after its termination an excretion urograph should be carried out to make certain that the kidney is functioning properly. If not a catheter should be passed up the ureter and retained for four hours. When urinary symptoms persist after pregnancy one should find whether there is any residual urine. If so, a catheter should be passed each day and the bladder irrigated with silver nitrate. This should be continued for five days after the residual urine disappears.

## Relation of Lymphatic System to Spinal Cord—

Gilchrist exposed the sciatic nerves of a series of rabbits and injected suspensions of various pigments in sterile distilled water into and round the nerve. After periods varying from a few hours to fifteen days during which the animals were allowed free movement, they were killed. The sciatic nerve, from the site of injection to its entrance between the vertebral columns, and the lower part of the vertebral column together with the spinal theca and cord were removed. After decalcification in Perle's solution for the requisite time, the bone was cut away and microscopic preparations were made of the nerve trunk, theca and spinal cord. The experiments indicate that particulate matter as distinct from fluids gaining entrance to the tissue spaces round the peripheral nerve or gaining entrance to the nerve bundle itself does not pass centrally in the endoneurium or between the individual nerve fibers for any appreciable distance. Bacteria of such size as to be within the range of microscopic vision do not commonly reach the spinal cord or its meninges by the lymphatic channels associated with the peripheral nerve trunks.

## Dysentery Produced by *Bacillus Pseudocarcinosis*—

Chopra and Chaudhuri isolated *Bacillus pseudocarcinosis* from the stools of forty patients twenty eight of whom had definite gastro intestinal symptoms. Nine showed the signs and symptoms of subacute dysentery of the bacillary type eleven suffered from diarrhea only two had constipation alternating with diarrhea, and six had pain in the abdomen. Another group of four patients were admitted with skin conditions pointing to intestinal allergic manifestations viz one had psoriasis, two had pityriasis rubra and one had urticaria. The remaining eight patients were admitted for other causes i e three had fever one diabetes one chyluria one myocarditis one anasarca and one an infection with *Tinea violaceum*. The last twelve patients although they were admitted to the hospital for other causes also suffered from definite symptoms pointing to gastro intestinal disturbance. Most of the patients complained of flatulence distention and vague abdominal pains. Some had tenderness in the epigastrium others showed symptoms of typical bacillary dysentery of a subacute type while still others suffered from chronic intestinal stasis with symptoms of constipation alternating with diarrhea. Roentgenograms showed stasis of the large intestine. Most of the patients were anemic. Microscopic examination of the stools revealed associated protozoa and helminthic infections. In the stools of nine patients *Endamoeba histolytica* was found in one a large number of spirochetes in six hookworm eggs and in seven *Giardia intestinalis*. In a certain number of these patients there were multiple infections but in none was a combined infection with *Bacillus pseudocarcinosis* and Flexner or Shiga dysentery organisms found. *Bacillus pseudocarcinosis* was isolated from all the cases. Agglutination was positive in eight cases five giving the reaction in a dilution of 1:160 one in 1:80 and one in 1:10. Negative results were obtained in twenty-one cases. The strains isolated were tested with stock dysentery bacteriophage in sixteen cases but only in eight were the bacilli lysable in vitro by the bacteriophage used. Even after treatment with bacteriophage the infection could not be eradicated in most cases and *Bacillus pseudocarcinosis* was isolated from the stools.

## Constitutional Abnormality of Polymorphonuclear

**Leukocytes**—Shaw describes a case of persistent left handed deflection of the polymorphonuclear count associated with an abnormally complex nuclear configuration of all the class I cells. There was no nuclear change in the other leukocytes and the total and differential counts were normal. It is claimed that the condition is a constitutional abnormality of the polymorphonuclear leukocytes. Hereditary transmission was not found, but the evidence is incomplete. No record of a similar case has been found in the literature and the condition differs in certain important respects from "Pelger's familial anomaly of nuclei". The annual curve of the total leukocytes is recorded. All the high peaks fall within normal limits but the polymorphonuclear count shows that some of them are physiologic and others are due to infection. There is no seasonal variation in the total leukocytes and the range of variation in the year is the same as in one person in twenty-four hours but less than in a population. The number of leukocytes is therefore a character of the patient. Oscillations of the annual total leukocyte curve were determined exclusively by the total polymorphonuclear cells. The variation in the proportion of the different types of leukocytes in the year is the same as in one person in twenty-four hours or in a population examined once and so the variation in the relative numbers is the same as in healthy persons. There is no seasonal variation and in this respect man resembles the pigeon. The total lymphocytes remained constant during the year. Solar radiation appeared to be the only factor that produced a seasonal variation. The relation of the annual curves of the total leukocytes, the percentage of polymorphonuclears and the percentage of lymphocytes was associated with the stability of the total lymphocytes. The total monocytes eosinophils and basophils showed no seasonal change. There was no seasonal variation in the polymorphonuclear count, which remained steady throughout the year unless disturbed by infection. The series of changes produced in the count by certain infections is recorded.

**Edema in Experimental Nephritis**—Dunn and his associates produced extensive subcutaneous edema and serous transudates in nephritis by corrosive mercuric chloride, potassium bichromate and uranium acetate when the renal lesions were severe enough and the animals ingested a sufficient amount of fluid. The greater liability to edema in uranium nephritis is probably due to the severe damage to renal structure and function which it causes, combined with low general toxicity and noninterference with nutrition. The essential cause of the edema in experimental tubular nephritis is failure of the kidney to excrete sufficient fluid. Oliguria is due to failure of the damaged renal tubules as conducting channels.

**Phosphate Excretion in Pregnancy**—Krieger investigated the value of the glycerophosphate test by the method of Bram and Key in a series of normal women, normal pregnant women and toxemic pregnant women. The test was compared with the blood urea and urea concentration tests. An analysis of the results showed no correlation between these renal function tests and the phosphate excretion. In several cases high blood urea, low urea concentration and low phosphate excretion seemed to confirm the agreement of the test with tests already in common use. On the other hand, many cases showing normal blood urea, normal urea concentration and a normal clinical history gave low values for the excess phosphate excretion. Again, many cases showing low figures for the urea concentration test and a normal blood urea showed much higher excess phosphate excretion than other cases in which the renal function, as assessed by the urea concentration test, was much more satisfactory. These results therefore show that this test seems to have no value whatever as a test for kidney efficiency in pregnancy. Even in normal pregnancy only 18 per cent of the patients examined showed an excretion of excess phosphate as high as 150 mg per hour, which is the value quoted as the minimal excess excretion for normal kidneys. In a small group of normal nonpregnant women the average excess phosphate excretion was 169 mg per hour, only one figure falling below the minimal figure of 150 mg per hour. In the toxemic group, only 5 per cent of the cases gave values above the minimum. There was only a 62 per cent agreement between the urea concentration test and the excess phosphate excretion, when 90 mg per hour excess phosphate excretion was arbitrarily used as the minimal value.

Mycosis Fungoides Report of Case L F Heimbürger—p 381

**Results of the De Rivas Treatment in Dysentery Cases**—Hemenway has used the De Rivas treatment in twenty cases of dysentery, amebic and bacillary, of which nineteen were cured and one was unimproved. The red cell counts of the group varied from 1,584,000 to 3,280,000, while the white cell counts ranged from 3,100 to 8,700, and the hemoglobins ran from 30 to 80. All stools contained blood and mucus. The treatment for the eradication of parasites of the large intestine is recommended for amebic and balantidic dysentery, trichomonas, oxyuris and other protozoa and metazoic disturbances of the large intestine. The patient lies on the right side with the hips elevated. An ordinary stomach tube is used for insertion in the rectum. This is connected with a glass Y tube, one end of which leads to an enema vessel and the other to a pail. There are stopcocks on both ends. The rectal tube is inserted slowly, and sufficient fluid is admitted to balloon out the intestine so the tube may be pushed up into the ascending and transverse colon, then a rectal thermometer is inserted. The enema vessel contains 5,000 cc of a 1:5,000 solution of copper sulphate at a temperature of from 52 to 55 C, which flows into the colon at the rate of from 100 to 150 cc a minute. A patient may be given 1 or 2 liters. When the patient complains of pain the enema tube is closed off, that to the pail is opened and some of the solution is drained off from the intestine. After this the treatment may be continued and at its close the patient holds it as long as he can. The treatment is given three times a week for two months and then once a week for a month.

**Action of Viosterol and Parathyroid Extract**—Spies and his associates studied the effects of vitamin D and the parathyroid principle on calcium and phosphorus interchanges in thyroparathyroidectomized dogs, with particular reference to any mutually related action which the two agents might have. They found that suitable doses of either viosterol or parathyroid extract elevate the serum calcium level, the curve of which approximately parallels those for the intensity of muscular responses to electrical stimuli and the urinary excretion of calcium. Within certain limits the serum phosphorus is inversely proportional to urinary phosphorus, serum calcium and urinary calcium. In general, the tendency of the parathyroid extract is to create a negative balance of calcium and phosphorus through increased elimination in the urine, while the tendency of viosterol is to produce a positive balance of calcium and phosphorus by the fecal excretion being diminished more than the urinary output is augmented.

**Cerebrospinal Liquid and Eyeground in Inguinal Lymphogranulomatosis**—Kitagawa observed the cerebrospinal liquid in thirty-seven cases of inguinal lymphogranulomatosis. In almost every case the pressure of the cerebrospinal liquid was abnormally high, but in the sitting posture it became variable and uncertain. The pressure in the prone position in seven cases was found to be from 200 to 420 mm of water and in two cases from 140 to 150 mm of water. Positive spinal fluid reaction for syphilis was indicated in nine cases, a positive Wassermann reaction in three and a positive Meinkke reaction in six. The colloidal gold reaction was negative in almost every case. The eye-ground was examined in thirty cases and edema in the fiber layer of the optic nerve surrounding the papilla, winding of blood vessels and increase of the capillaries were found in twenty-one cases. The causes of abnormality of the cerebrospinal liquid and of the eyeground are not clear, but the author believes that inguinal lymphogranulomatosis is a general disease affecting the central nervous system. Frei's skin test was carried out on 160 persons with the thought that the skin test was specific for inguinal lymphogranulomatosis, but Frei's antigen taken from the mixed inguinal lymphogranulomatosis was not an absolute specific, so that Frei's antigen should be made from the pus of pure inguinal lymphogranulomatosis.

**Plateau Form of Oscillometric Curves**—Vaquez and his collaborators discuss the oscillometric curves produced by the passage of blood through arteries. If an extremity is surrounded by an armlet containing air under pressure, the intravascular waves connected with the progression of blood produce oscillations in the gaseous medium which are easy to record. The normal state of the oscillometric waves thus obtained is expressed by a progressive rise followed by a progressive fall. Sometimes however the waves for a certain distance will be of the same height, and this phenomenon is called "plateau form." Abnormally narrow caliber of the artery or excessive volume of the blood wave are the only conditions that produce this type of wave. The authors were able to demonstrate this fact experimentally by the use of an apparatus described by Fabre. From the clinical standpoint the plateau form must be considered abnormal. It may usually be observed in patients with aortic insufficiency, pulse retardation (Adams-Stokes' syndrome) or arterial hypertension. In the case of aortic insufficiency the plateau form if not constant is at least frequent. By itself it is not a bad prognostic sign especially if it can be reduced by the usual methods or by immersion of the hands in hot water but complicated or of arterial origin the irreducible plateau form is an element of serious prognosis. The absence of the plateau form in arterial hypertension is a good sign. In general the authors believe that the existence of the plateau form of the oscillometric curve has a diagnostic, prognostic and therapeutic importance in patients having cardiovascular disease. It reveals unsuspected alterations of the arterial system with the hazards that they imply.

- \*Late Renewal of Functions of Diaphragm After Phrenicectomy R Jeanneret M Ribet and F Fame—p 748
- Immediate Massive Gastrectomy in Pyloric Stenoses J Duval—p 750

**Renewal of Function of Diaphragm After Phrenicectomy**—Jeanneret and his collaborators feel that the renewal of diaphragmatic function following phrenicectomy, usually performed for collapse therapy in tuberculosis recently reported by numerous observers, markedly increases the interest in the anatomic relations of the phrenic nerve. Frequently the tuberculous process simultaneously continues its evolution. Hence in some cases it is necessary to pass to another method of therapeutics and in others it is necessary to maintain the diaphragmatic paralysis as the best or sole method of therapeutic assistance. By reviewing the supply, course and anastomoses of the phrenic nerve, the authors conclude that this nerve and its accessories constitute the only route of motor and trophic innervation of the diaphragm. Consequently the removal of diaphragmatic functions necessarily indicates the reconstitution of a "circuit" uniting the cervical plexus to the diaphragm. Just how this occurs is difficult to determine with certainty. The available evidence favors regeneration of the phrenic nerve itself. If this is admitted, a second intervention on the phrenic nerve is legitimate to maintain the diaphragmatic immobilization. This would involve search for the principal regenerated trunk at the level of the old scar. If the search should fail, Goetze's operation should be performed. The latter would be based on the hypothesis that the nerve regeneration had involved a phrenic accessory rather than the main phrenic trunk.

- \*Clinical Study of Blood Urea-Urine Urea Relation J Cottet—p 762
- Rate of Glycemia in Negroes in French Equatorial Africa and Its Variations in Pathologic Conditions Pales and Monglond—p 765

**Blood Urea-Urine Urea Relation**—Cottet measures the urea in an exact twenty-four hour specimen of urine. The urea is also measured in a sample of blood taken at the end or soon after the end of collection of the urine specimen. The figures which express in centigrams the amount of blood urea are divided by those which express in grams the quantity of urea contained in the urine of twenty-four hours. The quotient of this division, multiplied by 100, gives the relation of amount of blood urea to the urinary urea. The value of this procedure depends on three factors: (1) the secretory power of the kidneys, (2) the quantity of urinary urea in twenty-four hours, which, in states of nitrogen equilibrium, is related to the quantity of absorbed albuminoids, and (3) the quantity of urinary fluid in twenty-four hours. The author concludes, as a result of more than 1,000 observations, that the value of the relation varies between 1 and 2 in subjects having a normal renal secretory power with the urea and aqueous twenty-four hour excretion at least equal to 15 Gm and 1,500 cc, respectively. Under these conditions the value is raised proportionately as the renal secretory power is diminished. The author concludes that this relation furnishes a simple means of evaluating the functional activity of the kidneys. It also shows the important part played by aqueous diuresis in the activity of renal functioning. The influence of aqueous diuresis on renal function and on urea secretion is well illustrated by the syndrome of azotemia of nonrenal origin with oliguria, the pathogenesis of which is thus explained.

- \*Studies in Pus Reaction A De Blasi—p 397
- \*Actinomyces of Gallbladder G Lino—p 418

**Studies in Pus Reaction**—On the basis of a colorimetric determination of the pus reaction of seventy-three patients with various pulmonary diseases, De Blasi found a hydrogen ion concentration of 7.29, a weak alkaline reaction in pus from chronic abscesses, and a hydrogen ion concentration of 6.22

a definite acid reaction, in pus from acute abscesses. Pus from chronic abscesses with mixed infection shows an analogous reaction to pus from acute abscesses. This difference in reaction may be helpful in the diagnosis of the nature of an abscess in doubtful cases. The author states that determination of the hydrogen ion will become simple and exact in the future. A high acidity rate in pus from chronic abscesses indicates a serious course and prognosis. Acidosis from pus of acute abscesses does not seem to be related to the micro-organism but is constantly in relation with diverse bacterial species. The acidosis is more intense in young patients. The author refers particularly to inflammatory acidosis and to the biologic significance of the abscess.

**Actinomycosis of Gallbladder**—Lino states that the great resistance of the epithelium of the gallbladder to Actinomyces at the lumen of the gallbladder explains why actinomycosis rarely occurs in that site. Actinomyces in the liver is sometimes eliminated with the bile and arrives in the gallbladder. But actinomycosis of the liver is a rare condition and thus is seldom transmitted to the gallbladder. Conditions capable of facilitating the implantation of the micro-organisms and diminishing the resistance of the cholecystic epithelium to the actinomycotic infection are infrequently found. There is little possibility of a rapid spontaneous cure of the actinomycotic granuloma.

New Trends in Medical Treatment of Hepatic Colic P. Alessandrini—p. 739

**Calcium Oxalate Crystals in Urinary Sediment**—Maugeri and Nico examined the urine of 100 subjects to determine the ratio of calcium and oxalate acid to calcium oxalate crystals. They found the crystals present in both alkaline and acid urine, but in larger amounts in the latter. The crystals were generally observed in urine with a high proportion of calcium. They usually occur in urine containing more than 30 mg of calcium per hundred cubic centimeters and seldom in urine containing less than 20 mg of calcium per hundred cubic centimeters. The rate of oxalic acid in the urine rarely amounted to more than 7 mg per hundred cubic centimeters. The authors consider the presence of calcium oxalate crystals in the urine an indication of altered oxalic acid metabolism. The crystals were not observed in urine which despite a high rate of oxalic acid, only presented a small amount of calcium. They define the presence of the crystals in the urine as calciuria and not as oxaluria.

\*Changes of Tongue in Gastrointestinal Ulcer M. Dobreff—p. 306

**Late Sequels After Bacillary Dysentery**—Ohly mentions the various infectious gastro-intestinal disturbances that occurred during the war and points out that among them bacillary dysentery is of especial significance because of its late sequels. When the history of a patient reveals that at one time he has had mucosanguineous diarrheas with tenesmus and fever, it is likely that he has suffered from a dysentery-like disorder. The anamnesis of many of these patients with postdysenteric disorders reveals that ever since the attack of dysentery the gastro-intestinal tract has not functioned properly. These persons complain of gastro-intestinal disorders particu-

larly after dietary mistakes and after exposure to cold. Bacteriologic examination of the stools generally gives negative results, but, since the agglutinins of dysentery are characterized by great stability, the serologic detection of a former dysentery may eventually become possible, but the author admits that fourteen or eighteen years after the attack of dysentery a positive serologic test is rare. However, even if both bacteriologic and serologic tests give negative results, a dysenteric sequel is nevertheless likely if the anamnesis discloses dysentery in the past history of the patient. Irritation of the mucous membrane of the colon is noteworthy in the symptomatology of the postdysenteric sequels. The roentgenogram occasionally reveals changes, particularly in the spastic-hyperalgesic forms, but a mild catarrh of the mucous membrane is not detectable by roentgenoscopy. After describing the pathologic aspects and the examination of the feces and the conditions of acidity of the stomach, the author discusses the fever and the incidence of gastroduodenal ulcers in postdysenteric disturbances. Foods containing large amounts of cellulose, or fatty and bloating foods, particularly when taken together with cold drinks, cause relapses. If the relapses are accompanied by fermentation dyspepsia, the author advises a day of fasting on which the patients take only black tea with some wine. Then follow three or four days during which all carbohydrates are excluded and a protein diet is given consisting of boiled meat, cottage cheese and eventually protein milk. If milk is given, it should be thinned with lime water. Then rice, toast and butter may be added and, after this diet has continued for eight days, cooked, strained fruits and vegetables are permissible, and later also mashed potatoes. Fresh fruits and bloating vegetables have to be excluded for several weeks.

**Changes in the Tongue in Gastrointestinal Ulcer**—Dobreff observed 147 cases of gastroduodenal ulcer for the epithelial defects of the tongue which Glaessner stated that he had seen in patients with gastroduodenal ulcer. The author found it in only one patient and concludes from this that the so-called ulcer tongue cannot have great symptomatic significance.

**Increase in Rest Nitrogen and Loss of Sodium Chloride**—Kohlschütter points out that it has become possible to differentiate a special form of uremia characterized not by distinct anatomic changes in the kidney but by a deficiency in its sodium chloride content. The shortage of sodium chloride may be produced by frequent vomiting, severe diarrhea or other conditions that lead to a loss of fluid. The question has been asked whether therapeutic measures, particularly salyrgan injections, which lead to a considerable decrease in the water and sodium chloride content, also produce an increase in the rest nitrogen. The author's investigations revealed that there is no such danger. However, in order to be sure in every case he recommends that whenever a high rest nitrogen value is found in the blood the sodium chloride content should likewise be determined, and he thinks that thus it will be possible to avert the danger of a chloroprivic azotemia.

\*Cerebrospinal Fluid Reaction J. V. Ambrus—p. 359

Symptomatology of Cerebral Disturbances in Whooping Cough V. Mikulowska—p. 364

**Demonstration of Encephalitis Virus by Vaccination of Cornea**—Rupilius and Szekely observed the corneas of rabbits that had been vaccinated with specimens of cerebro-

spinal fluid from twenty eight children with various forms of encephalitis. The aspects of punctate superficial keratitis were produced in only a few cases. The authors admit that the cerebrospinal fluid of encephalitis may produce on the cornea of rabbits a punctate superficial keratitis, but, since the inoculation of nonspecific solutions may elicit changes that do not differ from punctate superficial keratitis, the method can have no diagnostic value. In view of this, other conclusions drawn from this test likewise become untenable, for instance, it can no longer be maintained that acute aseptic meningitis is caused by the same virus as encephalitis.

**Cerebrospinal Fluid Reaction**—Ambrus discusses the cerebrospinal fluid reaction, which he described in the *Jahrbuch für Kinderheilkunde* (140 311 [Sept] 1933, abstr. THE JOURNAL, Nov 18, 1933, p 1684). To 1 cc of fluid is added 0.1 cc of a 2 per cent distilled aqueous potash soap colloid as well as 0.1 cc of a 20 per cent solution of sulphosalicylic acid. In the cerebrospinal fluids of healthy persons and in those from patients with acute cerebral and meningeal symptoms but without impairment of the meninges, a white turbidity develops which after a certain period gathers on the surface of the fluid in the form of a white ring from 2 to 4 mm in thickness, and the lower portion of the fluid gradually becomes as clear as water. In the meningitic cerebrospinal fluid however, the coarsely flocculated precipitate rapidly sinks to the bottom. Recently the author studied the turbidity and flocculation conditions of the cerebrospinal fluids of patients in whom the meningeal and cerebral tissues are histologically impaired. He observed that the slightest changes in the protein content are revealed by his test. In cases of meningism the extremely fine granular turbidity floats in the fluid for several days. There is neither sedimentation on the bottom nor adsorption on the surface. Different variations occur that are related to the severity of the disease process. Some turbidities rise to the border of the lower third or the middle of the tube and remain there. Occasionally there are coarser turbidities that float like a net. In the cerebrospinal fluids of patients with poliomyelitis or encephalitis, a characteristic micella-like precipitate appears. The more pronounced the inflammatory character, the closer the cerebrospinal fluid resembles that of meningitis. Variations are numerous, there are cases in which the micella net floats for several days in the fluid, while in others it settles on the bottom within several hours. However some micellas always remain in the fluid or adhere to the walls of the test tube. In the cerebrospinal fluid of basilar meningitis, a coarsely flocculated sediment quickly settles on the bottom. After fifteen minutes the precipitate has settled and after forty-five minutes the upper fluid is as clear as water. The author stresses the advantage of his method over other cerebrospinal fluid tests and expresses the opinion that the turbidity and flocculation are determined by the amount and type of protein. The rapidity of sedimentation is likewise important and increases with the quantity of protein.

- Experiments on Anaerobic Surface Culture. W. Bachmann—p 810

**"Blood Group Ferment" and Blood Group Substance in Saliva**—Satoh calls attention to the fact that in the feces and in the saliva processes take place that become manifest in a destruction of the blood group substance. These processes have been ascribed to the presence of the so-called blood group ferment. The author made further studies on the saliva first on that of the A group, and found that irrigation of the mouth

results in only a slight reduction of the blood group A substance and in an almost complete disappearance of the ferment action. Tests were made also on the saliva of the O group and it was observed that the group ferment directed against substance A is again largely removed by irrigation of the oral cavity, even though its disappearance is not quite as pronounced as in the saliva of the A group. These and other experiments seem to prove that the blood group substance rapidly reappears in the saliva or hardly disappears. The blood group ferment, however, is subject to great fluctuations and can be removed almost completely by simple irrigation of the oral cavity. The author thinks that these observations indicate that the blood group ferment in contradistinction to the blood group substance develops or increases autocathionously in the oral cavity.

**Ultraviolet Rays and Iodine Content of Blood**—To determine whether a seasonal factor, the ultraviolet rays, or the administration of ergosterol influences the iodine content of the thyroid and of the blood, Bennholdt-Thomsen and Wellmann made experiments on rats. They found that rats that have been exposed to the quartz lamp or had been fed with viosterol had a high iodine content of the blood (40.5 and 31.05 micrograms, respectively, per hundred cubic centimeters) and a low iodine content in the dry thyroid substance (112 and 167 micrograms, respectively, per hundred cubic centimeters). The control rats that had not received this treatment but had been kept in dark cages had a low iodine content of the blood (25.25 micrograms per hundred cubic centimeters), but large quantities of iodine in the dry thyroid substance (211 micrograms per hundred cubic centimeters). The histologic examination of the thyroids revealed that the ultraviolet rays as well as the administration of viosterol resulted in a flat, resting epithelium without increase in the follicles, but a considerable accumulation of colloid, while in the absence of these factors the opposite was the result, that is, an increase in follicles, restless and increased epithelium and decreased quantities of colloid.

- Capillary Reaction Following Sojourn on the Adriatic. R. Heller—p 843

**Gas Gangrene and Serotherapy**—Konjetzny points out that the value of the seroprophylaxis of tetanus is no longer disputed but that this is still the case in regard to gas gangrene. Some authorities have rejected it as entirely useless, while others have taken a stand against this depreciation of the seroprophylaxis of gas gangrene. The author reports nine cases of gas gangrene seven developed following a street accident and two following surgical interventions. These cases show that the administration of the anaerobic serum in its present form does not prevent gas gangrene, because it developed in four cases in spite of the prophylactic administration of the serum. The author does not consider it entirely useless. The cases described took a comparatively mild course as the result of the serum prophylaxis. In three of the cases Fraenkel's bacillus was the cause of the gas gangrene, and in two others Fraenkel's bacillus and Novy's bacillus were found. The author assumes that the German anaerobic serums do not contain a sufficiently large protective dose against Fraenkel's bacillus. Serotherapy following the development of gas gangrene comes usually too late, but in spite of this it should not be left untried. None of the seven cases of gas gangrene that developed following a street accident were fatal. In five cases the extremity was saved, while amputation became necessary in two. The author recommends the prophylactic as well as the therapeutic use of anaerobic serum in street accidents.

**New Seroreaction for Tuberculosis**—Meimcke reports that he has succeeded in preparing much better antigens than he employed for his first experiments with his clarification reaction for the serodiagnosis of tuberculosis. Moreover, in his first tests he employed only the centrifugation method, but these

improved antigens permit also a micromethod and a vault reaction. Four different antigens are used for the tuberculosis reaction: (1) a strong alcoholic tuberculosis antigen, (2) a weak alcoholic tuberculosis antigen, (3) an aqueous tuberculosis antigen and (4) an alcoholic control antigen, which is identical with the original standard extract for the Meinicke clarification reaction II. He discusses the significance of the seroreaction for tuberculosis. He maintains that it cannot be doubted that his tuberculosis reaction is a specific antibody reaction. The positive outcome of the test indicates either an active tuberculosis or that an active stage has existed until recently. The reaction may be helpful in the differential diagnosis, in the detection of cases of tuberculosis among larger groups and in determining the etiology of diseases of the eye, such as choroiditis and iritis, and of certain diseases of the bones and skin. In the prognosis the reaction may likewise become helpful, but it must be considered together with the clinical picture, for a reduction in the titer of the reaction may be a favorable as well as an unfavorable sign. Although the reaction has limitations, the author considers it a valuable addition to the diagnostic and prognostic methods.

Aortic Gymnastics. L. Roemheld—p. 767

Newer Studies on Radiation of Organisms. W. Stempel—p. 769

**Painting with Chloroform in Dermatoses**—Klingmüller noticed that painting with chloroform has a drying effect on the skin. In this respect it far surpasses benzine or ether. Moreover, it also has a certain bactericidal and fungicidal action. The author decided to try chloroform in various cutaneous disorders. In order to render the chloroform more stable he added 1 per cent of dehydrated alcohol, and, as the excretions of the skin generally have an alkaline reaction, he added a weak acid in the form of from 0.5 to 1 per cent of cinnamic acid. Hoping that the drying effect of the remedy would inhibit the growth of cutaneous fungi, the author decided to try it in the various forms of mycosis of the skin. He obtained good results in pityriasis versicolor, in erythrasma and in the interdigital mycoses. Many cases of suppurating cutaneous inflammations, such as acne and folliculitis and many eczematous dermatitides likewise responded to this treatment. Surprisingly favorable results were obtained in refractory cases of acne conglobata and in papular forms of acne rosacea. Later, the author tried the chloroform treatment even in chronic inflammatory changes of the skin, such as lupus erythematosus, and he obtained some favorable effects. He thinks that the treatment may be recommended in seborrhea of the face and of the head. The juvenile hard warts also frequently disappeared following painting with the chloroform preparation. An especial advantage of the preparation is that it does not cause discoloration. The chloroform evaporates shortly after the application, while the cinnamic acid remains in the form of crystals. The applications should be made from three to six times daily. The patient should be told to avoid inhalation of the chloroform. In case of open cracks of the skin the chloroform may come in contact with the exposed terminations of the nerves and thereby cause burning pains. However, many patients do not object to this if they will be relieved of the continuous itching.

**Chemical Exclusion of Surgically Exposed Sympathetic**—Doppler states that sympathicodiaphtheresis counteracts arterial nutritional disturbances in organs that have been impaired by vascular spasms. He finds that every lesion, induced on any portion of the peripheral sympathetic, reduces the tonus of the sympathetic locally and in the form of a reflex action becomes manifest as a depression in the tonus in other regions. The arterial dilatation is not limited to the comparatively short section of the vessels which has been treated but involves the entire vessel in the central direction and also peripherally. It involves neighboring vessels. Somatic

changes set in, which can be interpreted only as the results of a pluriglandular stimulation and which were produced by a reflex transmission of the arterial hyperemia to the vessels of the endocrine glands. In a discussion of the technic, the author employs a 4 per cent aqueous solution of phenol. Whereas formerly he only massaged the vessels with the solution, he has in the last four years combined with it the injection and infiltration of the periarterial tissues. He has discontinued the careful exposure and isolation of the arteries, for the solution penetrates the coats surrounding the arteries. He advises against a detachment of the adventitia as it is performed in Leriche's sympathectomy, for the removal of the adventitia predisposes to the formation of aneurysms and impairs the nutrition of the vascular wall. The attempt to reach superficial arteries by percutaneous injection, however, is inadvisable. The author performed sympathicodiaphtheresis on the common carotid, thyroid, left gastric, renal and pancreaticoduodenal arteries, also on the vessels of the hepatoduodenal ligament, on the arteries of the meso-ileum and the mesocolon, on the ovarian, uterine, spermatic, external iliac and femoral arteries and on the hypogastric plexus. He describes the technic of these interventions and discusses the indications for sympathicodiaphtheresis. He stresses its value in endocrine disturbances and mentions various other conditions in which the procedure proved helpful.

**Potassium and Calcium Content of Blood in Women**—Since certain symptoms of menstruation have been explained by an increased irritability of the parasympathetic nervous system, Schepetinsky decided to determine the action of the various phases of the menstrual cycle on the calcium and potassium content of the blood serum. He concludes that every laboratory has to develop its own potassium and calcium standard. He was unable to detect a menstrual vagotonia. He maintains that the fluctuations that occur during menstruation in the calcium content are negligible and remain within normal limits. The increase in the calcium content to the limit of normality during the premenstrual period and the decrease in the potassium are individual and have no relation to the constitution.

Action of Hormone of Anterior Lobe of Hypophysis on Nonfunctioning Ovaries of Women. R. A. Tschertok and G. W. Penkow—p. 146

Almost Full Term Interstitial Pregnancy. H. Tietze—p. 153

**Weltmann's Coagulation Band in Inflammations of Adnexa**—By means of Weltmann's coagulation test, Purper tested the serum of fifty-three women having adnexitis. The total number of tests was 173. They were made after weekly intervals, and their results were compared with the other signs of inflammation. In severe cases of adnexitis the author observed a considerably narrower coagulation band, while in mild cases the reduction was less. Changes in the inflammatory condition were accompanied by changes in the coagulation band. Moreover, there is parallelism between the coagulation band and the blood sedimentation and the number of leukocytes. Occasional divergences between the three reactions are due to the nature of these reactions. The author thinks that Weltmann's coagulation test is a valuable addition to the methods for exact diagnosis and prognosis of adnexitis. He considers it especially valuable in determining the advisability of an operation in case of inflammatory tumors of the adnexa, and he advises its use before curettage, in order to guard against flaring up of an adnexitis. In patients having menorrhagia the test should likewise be made before curettage.

Monatsschrift für Kinderheilkunde, Berlin

- \*Changes in Size of Liver in Nursing Toxicoses Anna von S Szasz —p 1
- Epidemiology of Scarlet Fever in Bratislava (Pressburg) A J Cbura and S Limbacherova —p 9
- Chloride Analysis of Organs in Young Dogs G Torok and L Neufeld —p 20

**Size of Liver in Nursing Toxicoses**—Szasz shows that in mild and medium severe toxicoses a protective "hepatic blockage," a swelling of the liver, sets in. The liver becomes enlarged and soft. Following administration of hypotonic solutions of sodium chloride the blood becomes thinner, the organism becomes detoxicated and the liver again attains normal size and consistency. Cases of toxicosis, in which the hepatic blockage is absent and the liver is small and thin, are rather severe. The erythrocytosis resulting from inspissation of the blood may precede the toxicosis by several hours or even days. In cases of severe nutritional changes, the number of erythrocytes is important and can serve as an early guide in the selection of the diet and the therapeutic measures. The secondary parenteral disturbances resulting from metabolic disorders are characterized by a high number of erythrocytes, and, if fasting is instituted early and large amounts of fluids are administered, a rapid cure may be obtained.

- Suppurating Meningitis Caused by Influenza Bacilli M Kasper —p 871
- \*"Secondary Vibration" a New Percussion Symptom in New and Old Disturbances of Vertebral Column A Stalman —p 873

**Tennis Elbow**—According to Boshamer, tennis elbow is due to an irritation of the periosteum of the lateral epicondyle of the humerus and is often limited to the lower edge of the epicondyle. If it exists for longer periods, periosteal deposits may become roentgenologically demonstrable. The median epicondyle is rarely involved. The cause is either a single direct trauma of the epicondyle or a continuous overexertion of the group of muscles attached to the epicondyle. The condition is frequent in persons who overexert these muscles, such as tennis players, cobblers, glass blowers, cabinetmakers, riveters, tinsmiths and washerwomen. Observations on forty cases convinced the author that the direct single trauma is more often the eliciting factor than the chronic irritation. The epicondylitis is characterized by a sensitivity to pressure of the region of the epicondyle, by a piercing and burning pain in the same region when the arm is stretched at the elbow joint to more than 160 degrees, and by radiation of the pains into the upper and lower arm and even into the fingers. Myalgia frequently coexists with the epicondylitis, and it is surprising that it frequently involves the antagonistic group of muscles, that is, the flexors. A circumscribed edema is present rarely. The main object of treatment should be to eliminate irritation of the periosteum, that is, every exertion of the extensor muscles attached to the epicondyle. A splint is applied to the upper arm and forearm while the elbow is bent at a right angle. Care must be taken that the wrist joint and the fingers are completely extended, but, if the median epicondyle is involved hand and fingers should be bandaged in the flexed position. To be able to influence the periosteal irritation with diathermy or with ointments that induce hyperemia, the author prefers the use of plaster-of-paris splints that are fenestrated in the region of the epicondyle. Immobilization should be continued for three or four weeks. Hohmann's operation may be resorted to because it produces results in a comparatively short time. Under local anesthesia an incision 3 cm in length is made over the epicondyle. The musculature on the anterior and lower rim of the epicondyle is notched. Then the cutaneous wound is closed. The after-treatment consists of a splint bandage left on for only about ten days. This operation was resorted to (1) in case of long duration of the disorder (2) when the disorder was caused by the occupation of the person, and (3) when the

conservative treatment failed. In the majority of cases the conservative treatment will bring the desired results. Similar conditions mentioned by the author are epicondylitis of the femur and tibia, periostalgia of the spinous processes of certain vertebrae, radial styloiditis and pressure periostalgias.

**"Secondary Vibration" in Disturbances of Vertebral Column**—Roentgenoscopy occasionally fails in the diagnosis of disorders of the vertebral column, particularly in anterior spondylitis. To find a more objective clinical method, Stalman employs the percussion of the spinous processes. Percussion of the vertebral spinous processes of a healthy person results in the "secondary vibration" of the subsequent and previous vertebrae. This secondary vibration is determined best by laying the tips of the index and middle fingers on the apices of the preceding and subsequent vertebrae while the other hand strikes the vertebra in between with a rubber hammer. The sound is not considered, but the touch detects the vibration. The vibration is more clearly perceived if the patient is lying face down, preferably over a bolster, or if he is in the knee-elbow position. When the examiner reaches a vertebra with spondylitic changes, the secondary vibration becomes considerably reduced or entirely abolished. However, if the spondylitic process has ceased and ankylosis has developed, the secondary vibration is again elicitable and, when the ankylosis has resulted in block formation, the secondary vibration becomes even more pronounced than it is in the healthy portions of the vertebral column. Thus "blocking" can likewise be detected with this method. Great intensity of the secondary vibration is found in spondylitis deformans and also in congenital blocking of several vertebrae.

**Specific Vaccine Therapy of Actinomycosis**—Neuber reports the case of a man, aged 27, who had abdominal actinomycosis. The intracutaneous vaccinations with specific vaccine resulted in specific allergic local, focal and general reactions, while the control vaccinations with physiologic solution of sodium chloride were negative as were also the specific vaccine injections of control persons. The specific vaccine therapy was effective. The patient recovered after ten injections. The vaccine was administered in doses beginning with 0.1 cc and gradually increasing to 0.9 cc. The intervals between injections were four or five days. In the course of this treatment the infiltrates became resorbed, the fistulas closed and the patient gained weight, so that he could be discharged as cured. Autovaccines or at least polyvalvaccines should be used. The vaccine is prepared from maltose agar cultures. When they are from three to four weeks old they are washed off with 5 cc of a sterile solution of sodium chloride. This suspension is subjected to trituration for about fifteen minutes and is filtered and 0.5 per cent phenol is added. It is stored in the icebox. The polyvalent vaccines are prepared from four or five different strains.

**Rapid Culture of Diphtheria Bacilli**—According to Sole, it was Folger who perfected a rapid culture method of diphtheria bacilli more than thirty years ago, but the method did not become known to the general medical public. The procedure is as follows. A sterile swab on a holder, as is used for taking smears from the pharynx or nose, is dipped into sterile horse serum (free from disinfectant) until saturated. The swab is pressed out against the side of the bottle and then it is turned over a flame until vapors develop and the serum-saturated surface appears slightly coagulated. The author employs horse serum while Folger employed beef serum. The swab thus prepared is passed over the fauces or into the nose of the patient. Then the swab is put into a sterile glass tube and placed in the incubator. The author emphasizes that the

swab should be prepared immediately before the smear is taken. Folger originally took the culture swab from the incubator after four hours, scraped the micro organisms that had grown on the swab onto a slide and examined them with the microscope. Later he reduced the incubation to three hours, and the author found that in 80 per cent of the cultures a two hour incubation was sufficient, but, after taking some of the culture after two hours, he puts the swab back into the incubator and after another two hours examines the rest of the culture. Simultaneously with the preparation of the culture swab, another smear is taken and, after staining, is immediately examined. The usual Löffler culture was made in all cases as a control and was examined after eight and after thirty-six hours. These control tests corroborated the results of Folger's rapid method in all cases. As stated, a diagnosis was possible in most cases after two hours.

**Admissibility of Blood Transfusion in Panagglutination.**—The case reported by Lewin raised the question whether it is permissible to give a blood transfusion to a patient with panagglutination. This case came to necropsy. A patient with a hepatolienal syndrome and splenomegaly was to be prepared for an operation by a blood transfusion. The determination of the blood group revealed autohemagglutination. The blood group O could not be determined until after elimination of the erythrocytes. The patient was given an infusion of 500 cc of blood of the same group and he tolerated it well, for there were no complications of any kind. On the following day, in connection with the splenectomy, there was a hemorrhage from the hilus vessels, which resulted in death five hours after the operation. The postmortem examination revealed the same manifestations of hemagglutination of the blood in the vessels and of the blood that had accumulated in the abdominal cavity as those noted in the determination of the blood group. The clinical course as well as the histologic examination disclosed no symptoms that could have been ascribed only to panagglutination. The author concludes that the status of the blood found on necropsy proves that the panagglutination is a cold agglutination and that, when the body becomes cold after death, the same processes take place as in vitro in the group determination. He maintains that the transfusion of blood of the same group is permissible in cases of panagglutination.

**Diagnosis of Carcinoma of Female Genitalia.**—Adler discusses the symptoms of carcinoma of the vulva, vagina, uterine cervix, uterus, uterine tubes and ovaries and reaches the conclusion that early diagnosis is difficult in nearly all carcinomas of the female genitalia, because (1) pains set in comparatively late, and patients as a rule do not consult a physician until pains are felt, (2) hemorrhages are not given sufficient attention or the women hesitate to consult a physician during the time of bleeding, (3) it always requires a certain lapse of time until a genital carcinoma shows any symptoms at all (latent period). Thus it is not entirely the fault of the physician or of the patient that so small a percentage of genital carcinomas is recognized during the beginning stages. The author thinks that a gynecologic examination after regular intervals would probably be a solution of this problem. In younger women such an examination should be made once a year or at least once in two years. In women near the menopause, the examination should be made every six months.

**Study of Bone Transplant.**—Camitz and his associates transplanted homologous fragments of the radius in seventeen dogs. The bony fragment with its periosteal covering was

transplanted from the right radius to the left and vice versa. The animals were killed after periods of from forty-eight hours to 196 days. The histologic sections were stained with Hansen's iron trioxylhematin-fuchsin S or with hematoxylin-eosin. It was found that a reaction in the periosteum of the graft is observable after seventy-one hours. After five days the proliferating connective tissue surrounding the graft assumes the character of a connective tissue callus and unites with the collagenous trabecular structure (myelogenous callous tissue) simultaneously developing from the endosteum of the host's bone. Periosteal callous tissue begins to form after another five days. While the connective tissue callus assumes more and more the character of a bony callus, the myelogenous callous tissue undergoes a powerful development within the marrow cavity and a periosteal callus develops close to the defect in the host's bone and opposite this area. The myelogenous callus disappears after forty-two days, but the periosteal callus persists. Definite degenerative alterations are present in the periphery of the graft after sixty days. At the same time the callous tissue inside the bony defect assumes more and more a definite lamellated bony structure and the periosteal callous tissue begins to break down. The authors believe that some parts of the graft are reformed during the process of union in this manner, while other parts retain their original structure. As the process of union of the graft progresses, the latter gradually assumes a definite lamellar bony structure. After 196 days there is little left of the original periosteal bony deposits. The osteoclasts appearing as the result of breaking down of the bone tissue can be seen on the surface of the graft after seven days. They may be observed 196 days later below the periosteum in areas in which the periosteal deposits are still present. Haggqvist's view of osteoclasts as secondary elements constituting the end result of osseous protoplasm deprived of calcium salts and collagen seems to be verified by the authors' observations. The periosteum and endosteum of the graft do not play a prominent part in the regeneration of the bone, though their presence and their vascular supply appear to be of great importance for an ideal union. A compact bone portion of the graft is retained for the most part. It will ultimately stimulate the surrounding tissues to new bone formation.

**Cholecystography.**—Foged reports 401 cholecystographic examinations made on 388 patients to whom 3 Gm of tetiothaleim sodium (iodotetragnost) was given either orally or intravenously, according to the method of Sandström. In ninety-seven normal persons without symptoms referable to the liver or the biliary tract, a normal cholecystogram was obtained in ninety-one, while in six there was absence of the shadow of the gallbladder. In 214 cases of cholelithiasis and cholecystitis pathologic cholecystograms were obtained in 191 and normal shadows of the gallbladder in twenty-three. Cholecystography in this group established a clear diagnosis in 30 per cent of the cases and was helpful in arriving at a diagnosis in 90 per cent. The author states that more than 80 per cent of normal cholecystograms are obtainable from persons without liver or biliary tract disease. A normal cholecystogram does not definitely exclude the existence of pathologic alterations in the biliary tract. A pathologic cholecystogram indicates a disease of the liver or the biliary tract in 90 per cent of the cases but a pathologic cholecystogram may be obtained from a person not suffering from any disease of the liver or the gallbladder.

**Poisoning from Food.**—Serologic examinations made by Huss and Lindström showed that the intoxication which affected about fifty persons who had eaten in the lunchroom of a railway office building on the date in question was probably an acute intestinal disorder due to dysentery bacilli of the Kruse-Sonne type, the source of infection being sliced boiled ham that had been contaminated by an infected food handler.

## OBSTETRICS VERSUS MIDWIFERY

CHAIRMAN'S ADDRESS

JOSEPH B. DE LEE, M.D.  
CHICAGO

The dictionaries say that the terms obstetrics and midwifery are synonymous but I would draw a distinction between them. The term midwifery should apply to the practice of caring for women during childbirth by the old blind, empirical methods, while the term obstetrics should connote the fact that to the wisdom gained by experience has been added all the knowledge supplied by recent scientific investigation. In short, midwifery is the practice of midwives, male and female, and obstetrics is the practice of the scientifically trained physician.

For many centuries the midwife reigned supreme in her field, and only on rare occasions did the surgeon-physician intrude—and then his accomplishments were not praiseworthy—for which not himself but the customs of the times and the degradation of women were to blame.

Hippocrates, whose mother was a midwife, and he the son of a line of physicians, knew very little about childbirth. He thought the child somersaulted into a vertex presentation, at about the seventh month of pregnancy, and every month braced his feet against the fundus uteri and tried to leap into the world. Though his knowledge of the mechanism of labor was little and faulty, he organized midwife teaching and gave a classic description of the death from puerperal peritonitis of the daughter of his friend Telebulos.

For many centuries men were forbidden access to the birthroom and had to get their knowledge of birth from animals. Therefore when called to a complicated labor all that they could do was to destroy the fetus and extract it piecemeal—and the instruments they possessed were crudely destructive. True the Jews, about 200 years before Christ, had done cesarean sections and some of the women and children had survived, but the operation had a terrific mortality.

For 1,500 years after Christ, midwives and slave doctors had almost complete sway in the delivery chamber. The midwives pursued every device to retain their control, and the doctors could learn nothing of normal delivery. The fact that they were helpless in obstructed labors, except for their destructive instruments made their situation worse, because, as Smellie said, the women took great alarm when a man midwife was to be called, since they knew that then either the mother or the baby or both were lost.

In 1509, Pare reinvented podalic version and midwifery practice by men began to improve. About 1664, Louis XIV insisted that his friend Dr. Clement be allowed to deliver his mistresses and at the court the influence of the midwife began to wane. In the sixteenth century, Dr. Werth of Hamburg was burned alive for having attended a normal labor in disguise, the midwives enjoying a "racket," and in several lands the contest between doctors and midwives for the control of the lying-in room still persists.

The invention of the obstetric forceps, about the beginning of the eighteenth century, gave the greatest impetus to the movement to have men attend women in labor, but until very recently the practice of normal obstetrics by physicians has been looked down on by the profession and by the public as well as by the midwives.

Labor was considered a normal harmless function not requiring the attendance of anybody but one capable of cleaning up the soil afterward, and therefore it was beneath the dignity of a real physician.

In Germany, in 1751, Roederer publicly demanded that the same dignity be accorded the accoucheur as the physician and surgeon but he received little acclaim.

This disesteem in which obstetrics has always been held adverted to the doctors who felt the desire to be helpful to the distressed woman in labor. In England they were dubbed men-midwives, and some of the men who have left illustrious names in Britain's medical history were held in contempt during their lives.

Astonishingly, as late as 1825, a man-midwife was denied admission to the Royal College of Surgeons, and his friends would not be seen shaking hands with him on the street, indeed, thus complains Ramsbotham, one of the British obstetric luminaries of the nineteenth century. Queen Victoria had midwives for her earlier labors. In 1850, when Dr. White of Buffalo delivered a woman before a class, he was denounced by the press and his own profession, and tracts were circulated declaring that "the employment of men to attend women in childbirth is unnecessary, unnatural and injurious."

As with the practice, the science of obstetrics and its teaching lagged behind medicine and surgery. Semmelweis, Pasteur and Lister showed how to prevent puerperal infection and Simpson gave woman anesthesia. Now, armed with the obstetric forceps and these two, which were soon followed by cesarean section, the obstetrician felt that he was master of the birthroom.

But some of the old opprobrium still clings to the obstetrician and his work. The public in many places still believes that his accomplishments are less than those of the medical man and the surgeon. The medical schools, in many universities, still rate obstetrics as a minor specialty, and even today students leave their

campuses with a debased opinion of the science and art of obstetrics, which opinion is bound to result in an inferiority of the work they will do

Hospitals do not provide facilities for obstetrics that are the equal of those for surgery. Let any one compare the surgical operating room with the delivery room in his own hospital, and let him think over which one receives the most service

All my medical life I have striven to eradicate this low opinion of obstetrics and to place on equally high pedestals the three primary branches of medicine, obstetrics, medicine and surgery, all equally important, all equally dignified. Of course I have not been alone in this endeavor. Jaggard, my predecessor at Northwestern, Hirst in Philadelphia, Williams in Baltimore and many others have been waging the same fight and a great deal has been accomplished

It is therefore with great pain and some alarm that I notice a trend in Britain and in spots of our Eastern seaboard, a reactionary trend, toward the state of midwifery. Perhaps I had better make known the grounds for the claims, which some might call extravagant, that I make for obstetrics as opposed to midwifery. In other words, let a scientific examination be made of this function which the medical profession is asked to turn over for safe conduct to persons taken from the ignorant classes, without college educations, without cultural development, unschooled in the fundamental sciences of medicine, untrained in the practice of medical and surgical and obstetric arts, blind watchmen at the bedside of birth and death. Indeed the mere hint of such a reversion offers an insult to one's intelligence, than which there is no greater affront

#### DISTURBANCES OF PREGNANCY

When a woman becomes pregnant she at once begins to undergo changes that affect every organ and every fiber of her being, and since these changes readily pass over into the pathologic, it is vital to her health that her physician know what is going on

Making only mention of *emesis gravidarum*, which in its varying degree is quite common, I would call attention to tuberculosis, heart disease, latent kidney disease and mild toxemias, of which hypochromic anemia is one. The term *hydremia* which older writers applied to the blood in pregnancy, has been learned to be known as *toxic anemia*, and it is responsible for not a few disturbances in pregnancy and labor. It seems to become worse with multiparity. In some cases it is the sequence of a focal infection, and a search for its cause may lead to the discovery of an endometritis, a pyelitis, a nephritis, appendicitis, gallbladder infection, abscessed tonsils or indeed an endocarditis

In these obscure often hidden, conditions may be found the causes of some cases of *abruptio placentae* and *autogenous sepsis* during and after labor. In women suffering anemias during pregnancy, one should look out for postpartum hemorrhage, thrombosis, embolism and puerperal infection. There is also good ground for suspecting that infectious foci may upset the endocrine balance and thus cause eclampsia and allied toxemias or disturb the water balance by the changes effected in the kidneys and liver, leading to metabolic complications. How it happens is not known, but there seems to be a relation between toxemias and latent sepsis

The fetus requires careful attention during pregnancy. Syphilis needs only a single word. What to do for that is well proved, but the nutrition of the baby

must be thought of and it must be protected from infection. Infectious foci in the mother can cause abortion, monstrosities, *abruptio placentae* and *placenta praevia*. It is necessary to learn how to protect the fetus from hemorrhagic diathesis, fragility of the blood vessels, which invites cerebral hemorrhage even during easy delivery, imperfect dentition, rickets, and an effort is being made even to find out how to develop its immunities against all the infections that beset it during and after birth. Truly this is a large order, indeed a reaching for the sun, but this is only one of the hopes of prophylactic obstetrics

#### LABOR

As far as the mother is concerned, the most important question the scientific obstetrician must answer is: How does the patient stand on the threshold of her labor?

1 Has she been cured of all the major and minor diseases that threaten her and her baby? I have just mentioned a few

2 Has her mind been prepared for the mental ordeal through which she is about to pass? The element of fear must always be taken into account in prenatal care and cannot be tossed aside with deliberate neglect or a casual slighting remark

Fear is a real menace to the well being of every pregnant woman, fear of death and fear of pain. Fear of death has caused many cases of postpartum shock and actual dissolution and fear of pain, which throws off the equilibrium of the sympathetic and autonomic innervation of the uterus, has caused many cases of physical dystocia, which have eventuated in forceps, lacerations, postpartum hemorrhage and maternal and fetal deaths from injury and sepsis

Fear of pain and pain itself can cause hypopneuphemia, and thus some postpartum cases of shock are explained. It would be silly to deny that labor is attended by pain, but the amount of actual suffering varies in different women

A large part of the pain in labor is subjective and is due to the changes, cultural changes, which are mostly mental, in the human female resulting from civilization, and a part is undoubtedly due to suggestion by the friends of the parturient and by the magazine publicity, which is so profuse at the present time. A small part is due to local anatomic changes produced by the mode of life, racial mixtures and disease

There is much reason for believing that if women could return to a more natural, primitive state, mentally and physically, their labors would reassume the known qualities of the function among primitive peoples, and the element of pain would show a corresponding decrease in intensity. I agree with Dewees and Grantly Read that the pain of labor is pathologic

In addition to the element of fear there are variable limits which nature sets in women as to their ability to endure pain, wakefulness, and mental and nervous strain. A proper evaluation of this ability and the institution of treatment resulting from it will prevent most cases of neurasthenia and the exhaustion psychoses, which at the present time are not uncommon

3 Has the parturient been brought into the best possible physical condition for the mechanical and metabolic strain of labor? How about her heart, lungs, abdominal muscles, pelvic floor and the connective tissue framework of the pelvis? How much work and stress can be expected of them? Has the woman "trained" for her athletic contest?

How about her liver, kidneys, hematopoietic system and hormonopoietic system?

4 How about the mechanism of labor? What kind of a motor is the patient's uterus? How is the cervix going to act? Only lately has it begun to be realized that the cervix causes much more dystocia than the pelvis. What kind of a pelvis does the patient have? It is easy to tell whether it is big enough, both at the inlet and at the outlet, but what is its shape?

Will it cause an occiput posterior position? Is it one that calls for a version, or if forceps becomes necessary should the occiput be brought out over the perineum instead of the orthodox way from under the pubis? Or is it one in which one of the later styles of forceps should be used, or indeed the forceps operation be never even attempted? Or is the pelvis such that, if the breech presents, the obstetrician should flex the head in leading it into the inlet, or deflex, or lateriflex it, or perhaps deliver with the chin toward the sacrum or to the pubis?

5 And the baby. Is it too large, too small? Does it lie well for engagement? Is the head flexed, deflexed, synclitic, asynclitic? If it is a breech is the spine curved, straight, are the legs extended, is the head flexed, deflexed?

Many of these conditions can be learned by roentgen study of the woman in labor and it will not be long before every up-to-date maternity will use radiography in the birthrooms.

All these and many more things the intelligent obstetrician must know at the time when labor declares itself, in order to plan the conduct of labor scientifically. And on his knowledge or ignorance of them will depend the life and health of the mother and of the baby, and it is this knowledge or ignorance that makes one of the distinctions between obstetrics and midwifery.

Another difference between the two modes of practice becomes evident during the conduct of labor, and here is the place to call attention to the abuse of the "test of labor." Jaggard introduced the term "watchful expectancy" as a principle of the conduct of labor. He distinguished sharply between a masterly inactivity and a supine waiting policy, but unfortunately the test of labor has often become, as one of my residents described it, "hopeful procrastination."

I should like to modify Jaggard's phrase to "intelligent expectancy," and by this I mean that all the conditions set down in the five numbered preceding paragraphs have been intelligently studied and then after a careful sifting of the factual observations a definite course of expectancy has been decided on.

What is seen most often is that when the patient goes into labor, she is allowed to suffer until irremediable damage has been done to her and her baby. Then the test of labor is said to have failed and cesarean section or some other inappropriate measure is employed. The time to decide on cesarean section is at the beginning of labor and if a preliminary test is to be given it should be short. A well qualified obstetrician does not need a very long time to prove to himself that a natural termination of labor is not to be expected and also whether such a long process can end with a healthy mother and a healthy baby.

Prolonged labor affects the mother in many ways. First it wears down the nervous system favoring in predisposed subjects, neurasthenia, exhaustion, psychoses, even puerperal insanity. It is also a psychic shock which influences the woman's whole life and may

prevent further childbearing and marital unhappiness, even divorce.

Prolonged labor, especially after the bag of waters is ruptured, is one of the most fertile causes of pelvic infection. Owing possibly to hormone changes in the cervix and vagina, which, according to Miura, Loeser, Cruikshank, Sharman and others, affects the glycogen content of the vaginal epithelium, or to the variation in the hydrogen balance, altering the acidity, or to the wandering of bacteria through the rectovaginal septum, or to all three of these, the bacterial flora in the vagina acquire invasive qualities. I shall speak of infection again.

Protracted labor has undeniable effects on the endocrine and metabolic systems, and this is true even in the first stage in which only the uterus is engaged in muscular work. Worry, prolonged moderate physical exertion, sudden overwork unbalance the suprarenals, the thyroid and the pancreas. The cerebral congestion that is so visibly marked in the second stage of labor must have some effect on the pituitary gland.

A "solar plexus" blow can lay out a fighter. During labor the organs in the upper part of the abdomen receive many blows. Theobald has shown that the function of the liver is much affected by increased intra-abdominal pressure, and this influence the pancreas also feels. Hyperinsulinism and hypoglycemia must always be thought of during labor and particularly in cases of shock post partum. The weakness, nervousness, "gone" feeling in the epigastrium, the state bordering on collapse, the tremor, the pallor, the sweating may be cured by the giving of dextrose.

The effects of muscular effort must be remembered. Any medical director of athletics knows that ketosis, dehydration, increased viscosity of the blood, dechlorination and finally acidosis will result from prolonged muscular exertion, especially in hot weather when sweating is profuse. These conditions exist during labor and unless relieved by food and water and salt may have serious consequences, indeed, such are much more likely if the acidosis of anesthesia is superadded.

To allow a labor to become unduly prolonged is midwifery, and how often does one see it!

Another familiar example of midwifery practice is the neglected high occiput posterior. Usually the gravida has been allowed to go over term and the baby is overgrown and hard. The bag of waters ruptures, the head remains high, with the occiput behind the transverse diameter, in moderate deflexion, and occasional asynclitism, the cervix remains long and often hard, the vagina is tight, the pelvic floor rigid, the pains are erratic in time, strength and regularity. I confess that these are among the most perplexing cases for which to pick out a line of conduct, but one must decide early exactly what one is going to do and, if abdominal delivery is rejected one must not let intelligent expectancy become hopeful procrastination. If one does the result is, after several days, arrest of labor with a thick undilated cervix, the head near the midplane, the mother exhausted, probably infected. Then, too late for section, the case is terminated by Dührssen's incisions, high forceps, episiotomy, postpartum hemorrhage and an injured or dead baby.

#### A NATURAL DELIVERY

In a natural delivery, under strong pains the head is forced through the bony pelvis. Putschar, on the examination of eleven women dead shortly after delivery, found that the pelvic joints always showed signs

of damage, hemorrhages and tears of the binding tissues and clefts showing in the pubis. Later come backache and arthritis.

The state of the cervix after labor is notorious. Its evils are well understood. One of the consequences of cervical injury and the infection that almost invariably accompanies it is parametritis postica, an inflammation of the uterosacral ligaments, to which in America, too little importance is attached. Another sequel of cervical infection is paraproctitis, which may advance even to mesosigmoiditis or colitis. All these conditions may be the cause of backache, constipation, hemorrhoids and invalidism.

I can only mention the damage labor makes on the pelvic connective tissue framework, and the frequent rectocele, cystocele, descent of the uterus, patulous vulva and low grade infection with the long and wretched trail of symptoms, which, while they do not incapacitate them, destroy the pleasure of life in so many women and which add to those conditions that make for domestic and marital unhappiness. Women are used up in bearing children and many husbands don't like an ailing, unresponsive wife.

Now how about the baby? From the very beginning of labor its troubles begin. Every uterine contraction forces blood into its vascular system and gives its heart a slight overload. This is augmented after the rupture of the bag of waters. Thus perhaps may be explained some of the cases of atelectasis following delivery, and the peculiar metabolic disturbances of early life.

Guttner made experiments on guinea-pigs placed in a pressure chamber. They are crude but they have some value. He found that intracranial pressure is increased with each pain, owing to overfilling of the cerebral vessels. Slowing of the heart is due to cerebral pressure, increase of carbon dioxide, which irritates the vagus, and increased arterial tension. The brain therefore suffers the effects of a vicious circle, which are local acidosis, edema, cyanosis, increased fibrinogen in the blood, chemical changes in the brain, and minute and larger hemorrhages. All these effects reach the highest point after rupture of the membranes and at the end of the expulsive stage, which really is often an explosive stage.

The attention of those who recommend the routine rupture of the membranes at term night, with much fitness, be called to the foregoing observations.

During delivery the child suffers somewhat as do caisson workers, and the compression during its passage and decompression on emerging may be attended by shock and coma and hemorrhages in the brain and other vital organs. The liberation of nitrogen in the fetal tissues, to complete the picture of caisson disease, has not been proved.

These hemorrhages occur often enough in regions that make it possible to locate them clinically, but since the mind, the reason and the will develop later in life, one cannot say how often destruction of portions of the brain governing these functions has occurred during birth. I believe it happens very often, and one of the grounds on which I base this belief is my own observations of the better health of children delivered by cesarean section compared with those entering the world through the natural passages and from analogy. Men after suffering asphyxia, as from drowning, automobile exhaust gas, carbon monoxide and concussion of the brain, often suffer weakness of memory, acalculia, headaches, aberration of the will and even grave mental disorders.

I am afraid I may be accused of having drawn too dark a picture of the dangers attending and the disabilities following childbirth, and that my notice may be called to the great numbers of women who have had large families and apparently are none the worse for it. I agree to a considerable extent, but I wish to call attention to the immense army of women suffering, if I may coin the phrase, subinvalidism and who say they have never felt well since their first baby was born. I wish to signalize the not inconsiderable number who date permanent kidney disease from a mild toxemia in pregnancy, or permanent liver damage or suffer the sequelae of dislocation of the pelvic organs, to which I have made brief reference.

I painted a true picture of pregnancy and parturition, using the colors supplied by modern science, to prove that obstetrics is a richly scientific member of the triumvirate of medicine, that it has become an art of great technical beauty and that its proper practice is far beyond the capabilities of the midwife, male as well as female. I have shown only a part of the knowledge a man must have to qualify as an obstetrician, and it is this knowledge and the application of it that make the difference between obstetrics and midwifery.

I desire to emphasize with all my might that these remarks do not mean that every labor must be terminated by mechanical art. With present knowledge and present means there is only one place where operative intervention can improve on nature in normal delivery, and that is in preventing damage to the pelvic floor. In all else it is safer to guide the labor along natural channels until dystocia becomes threatening or immediate.

Letting a woman pound the head on the pelvic floor for hour after hour is midwifery by omission.

Doing routine version and extraction is meddlesome midwifery, unscientific and pernicious.

Blasting the baby through the birth canal with solution of pituitary is meddlesome midwifery, unscientific and pernicious.

Cesarean section selected properly may be the finest kind of obstetrics, comparable to a scientifically conducted normal labor, but as it is performed today it is often an exhibition of the lowest obstetric intelligence, of which even a midwife would be ashamed. In the fifteenth century, midwives did cesarean sections.

The present is an era of prophylaxis. As Farbairn has said of prenatal care, the aim must be a constructive regulation of physiologic function as much as the prevention of pathologic conditions. The conduct of labor must meet the requirements of modern womanhood. The woman nowadays demands a safe labor, freedom from unnecessary pain, a reasonable length of labor and, when she arises from her confinement, a complete *restitutio ad integrum*.

She also demands a healthy baby, undamaged by conditions affecting it during pregnancy, and free from the effects of traumatism during labor. Modern obstetrics can give the woman nearly all these things, and the people are willing to pay for them. They should not be given a midwife's services and be asked to pay an obstetrician's fee. Hospitals must turn out enough highly trained men to establish and maintain the ideals I have described, and here is where I must come down to earth.

#### ATTAINMENT THROUGH EDUCATION

There are not enough schools, teachers, material or public and professional support to supply real obstetricians for 2 000,000 births each year.

Fortunately the principles of the conduct of labor are not difficult to master. Nature is still on her job and, though perhaps somewhat destructive, she can do it better than unskilled human beings. Let doctors be taught the beauties of normal obstetrics, the principles of asepsis and the principles of intelligent expectancy, trusting much to nature. There will soon be a reduction of the national maternal mortality and morbidity.

In the meantime the medical profession can hold the vision of its ideals and struggle to attain them, and it will attain them only through education—education of the medical schools, of the universities, of the doctors and of the public.

## SARCOMA OF THE UVEAL TRACT FOLLOWING TRAUMA

EDWARD STIEREN, M.D.  
PITTSBURGH

The adoption of workman's compensation legislation in this country and abroad has brought to the fore an ever increasing number of petitions for compensation, the claim being made that a local injury is responsible for the subsequent development of a malignant growth in the part affected.

During the past decade, surgeons and pathologists in general have altered their views in regard to trauma and malignancy, now accepting the causal relationship. Many judicial opinions have been rendered in favor of the issue and the causal relationship is accepted by courts and compensation bureaus everywhere.

That there are dissenters from this view is attested by the opinion of Dandy,<sup>1</sup> who stated that, since sarcoma had never been produced experimentally by trauma, he did not think that injury had any bearing on either its cause or increased propagation.

It is significant to observe that in this instance the commissioner ruled for the plaintiff and against the testimony of Dandy.

In a study by Herbert Fox,<sup>2</sup> based on an analysis of 6,500 autopsies on animals and birds in the Philadelphia zoo, is the statement "Slye and Wells report facial neoplasms in mice arising at points of old injuries."

Coley and Higinbotham<sup>3</sup> make the following observation:

In France the whole question took on importance from a medicolegal standpoint as early as 1897. Then the first law was passed. This outlined certain conditions the fulfillment of which meant the establishment of a causal relationship between an antecedent local trauma and a subsequently developing tumor. In 1907, at the French congress of surgeons, Segond read his classical paper on the subject, in which he presented six conditions, which conditions or rules have been accepted not only by the courts and compensation bureaus of Europe but of America as well. They have been accepted by Ewing in his book on "Neoplastic Diseases."

These conditions imply the following: (a) The authenticity of the trauma. (b) Sufficient importance or severity of the trauma. (c) Reasonable evidence of the integrity of the part prior to the injury. (d) Correspondence of the tumor to the

site of the injury. (e) A date of appearance of the tumor not too remote from the time of the accident to be reasonably associated with it. (f) A diagnosis established by clinical and roentgenological evidence, supported when possible by microscopical examination.

In the field of ophthalmology, no definite stand has been taken on the question, although the earlier writers seem to attach little importance to it. Thus Parsons<sup>4</sup> states "There was a history of injury in twenty-nine of Fuchs' cases (11 per cent) and in five of Lawford and Collins', there is no sufficient evidence that it is of etiological moment. There is rather more evidence in favor of prolonged inflammation, but analysis of the cases in which the conditions are combined tends to minimize its importance."

The infrequency with which trauma is mentioned in the literature on malignancy of the eye during the past thirty years is impressive, and causes the making of such observations to appear remiss. Of the few cases that I have been able to find in which trauma is mentioned as a causal factor, the earliest is by Coleman<sup>5</sup> in 1901. The patient, a man, aged 23, was struck in the eye by an exploding gun cap. Eight months later an elevation on the iris was excised by an iridectomy and microscopic examination by Dr. Brown Pusey showed it to be sarcoma. There was no recurrence.

Fig. 1—Original single injury laceration of conjunctiva by the head of a nail.

Kipp<sup>6</sup> reported before the American Ophthalmological Society in 1905 a case in which, after enucleation, a melanosarcoma extending from the ciliary body to the disk was found. The patient was a man, aged 40, and the eye had been injured at the limbus by being struck with a fragment of wood three months before.

Ball and Lamb<sup>7</sup> report a case of epibulbar tumor occurring sixteen years after the patient was struck in the eye by a snowball. After the injury a brown spot remained on the temporal side of the sclera. It gave him no trouble until six months before admission, when it began to grow rapidly. It was excised six weeks before and had recurred rapidly, now measuring from 9 to 12 mm vertically and from 13 to 16 mm horizontally, reaching a height of 6 mm. The eye was enucleated and a microscopic diagnosis of melanosarcoma was made. The rapid recurrence of the sarcoma after excision emphasizes the importance of thorough removal with wide inclusion of healthy tissue in epibulbar and adnexal growths of this type. Following excision, roentgen or radium therapy within the limits of skin tolerance should be repeatedly applied to the operative site.

3 Coley, W. B. and Higinbotham, N. L. Injury as a Causative Factor in the Development of Malignant Tumors. Ann. Surg. 98 991 (Dec.) 1933.

Nitsch's<sup>8</sup> patient was a girl, aged 15, who was struck on the temporal side of the eye by the shaft of a rake. No subjective or objective symptoms appeared at the time, but after a week it was noticed that the vision was failing. A year later the eye became inflamed for the first time. A diagnosis of intra-ocular tumor was made and the eye was enucleated. The laboratory diagnosis was melanotic sarcoma of the choroid arising on the lower temporal side.

Fig 2—Intra-ocular neoplasm arising immediately beneath the site of the injury

Chance<sup>9</sup> reports the case of a woman who consulted him in 1925 because of pain in a long-diseased eye, which had become a much shrunken globe. The eye suffered a trauma three years before and was never free from inflammation afterward. The eye was enucleated and a microscopic diagnosis of sarcoma was established. The patient died of a cancer of the stomach four years later.

Holloway's<sup>10</sup> patient was a man, aged 23, whose eye had been struck by a hammer three years before. No change was noted in the eye for a year, then the vision became impaired and steadily grew worse. With the ophthalmoscope a large, round and circumscribed detachment of the retina was seen extending over the macular region and far forward. The eye was enucleated and subsequent microscopic examination showed a mixed type of melanotic sarcoma of the choroid.

In a personal communication, Dr Holloway writes, "In regard to trauma, I believe I would probably agree with you. It may be with this case as with others on record that it had a definite etiologic connection. I think any of us see too few of these cases with trauma as a basis to form a definite opinion, but I am quite convinced that the analysis of the cases on record would show a definite incidence for trauma as a factor."

In a recent paper Dr Leila Charlton Knox<sup>11</sup> has furnished a critical study of the relationship of trauma and tumors. According to Knox, Segond,<sup>12</sup> discussing the statistical collections of case reports of tumors of alleged traumatic origin, doubts that they have any value and that they represent only "empiricism under a mathematical disguise, for the most extensive statistics when they are derived from a variety of sources

often have less value than fifteen minutes of good observation."

Ribbert<sup>13</sup> thought that the statistical collections were without value and stated that well studied single cases of this type might be more convincing than previously published statistics. With this sagacious observation in mind, I desire to report the following case.

#### REPORT OF CASE

G. L. H., a man, aged 58, was injured in the left eye by the head of a flying nail, March 6, 1923. There was a profuse subconjunctival hemorrhage with a vertical laceration of the conjunctiva and the subconjunctival tissue in the temporal region. Healing of the conjunctival tear and absorption of the hemorrhage took place in about two weeks and he was discharged with the eye in a comfortable condition and a visual acuity of 6/6.

He was not seen again until Jan 14, 1932, almost nine years later, when he appeared with the statement that the vision had been failing in his left eye for the past six months. On examination, the left pupil reacted sluggishly to the direct light stimulus, there was a moderate conjunctivitis and the tension was reduced to 12 McLean (right eye, 20 McLean). The iris reacted feebly to atropine. A detachment of the retina extending well forward on the temporal side was readily seen with the ophthalmoscope and by reflected illumination. This area did not transilluminate from the limbus to well beyond the equator.

A diagnosis of intra-ocular neoplasm was made and the eye was enucleated February 1. The globe was sent to Dr Ramon Castroviejo Jr, who submitted the following report.

The eye was received with the diagnosis of intra-ocular tumor. By transillumination there was a shadow, which was located toward the temporal side in the upper quadrant, extending from the ora serrata toward the equator of the eye. The dimensions were 12 mm in the anteroposterior axis and 9 mm vertically.

Fig 3—Melanotic sarcoma of the choroid (melano epithelioma)

Two segments were cut in the sclera above and below the equator of the eye. The eye was fixed in a mixture of equal parts of formaldehyde and Muller's fluid, and sections were made horizontally.

Macroscopic examination revealed a growth at the temporal side of the choroid extending from the ora serrata toward the equator of the eye. The retina was detached in this location, owing partly to the tumor and partly to an albuminous exudate. The detachment was circular extending from the ora serrata

13 Ribbert M W H Deutsche Ztschr f Chir 1898 p 574

toward the equator of the eye. The rest of the structures of the eye appeared to be normal.

Microscopic examination showed the following facts. The cornea was normal. Schlemm's Canal was filled with red blood corpuscles and a number of leukocytes. In the angle of the anterior chamber there were a few deposits of pigment and toward the temporal side there was a slight adherence of the iris to the posterior surface of the cornea, closing the angle at this point. The ciliary body and the choroid were edematous, and the blood vessels were dilated. Toward the temporal side starting at the ora serrata there was a tumor, which extended to about 3 mm beyond the equator of the eye. The tumor was flat and was located entirely in the choroid. It was composed of round cells, rich in chromatin, with little cytoplasm and large round or oval nuclei, with large nucleoli. The cytoplasm of some of the cells contained granules of brown pigment. In certain places the accumulation of pigment was so heavy that the structure of the cell could be distinguished and the appearance of a mass of isolated pigment was given. The tumor had blood lacunae lined with endothelium. There were also a few blood vessels. The retina was attached to the central portion of the tumor and its different layers were degenerated. There was an albuminous exudate on both sides of the tumor, detach-

Fig. 4.—Melanotic sarcoma of the choroid (melano epithelioma) reduced from a photomicrograph with a magnification of 600 diameters

ing the retina circularly around the ora serrata. The other structures of the eye were normal.

The diagnosis was melanotic tumor of the eye.

In making the diagnosis, Dr. Castroviejo commented that melanotic tumors of the eyes are classified as melanosarcoma by certain writers, but modern authors have a tendency to consider that all these melanotic tumors have their origin in wandering cells detached from the neural epithelium, therefore they should be called melano-epitheliomas instead of melanosarcomas.

The six conditions stipulated by Segond are present in this case and I have no hesitancy in ascribing the malignant growth in the choroid to the external injury to the eye nine years before.

There has been no recurrence of the growth in the orbit and no evidence of metastasis in two years.

515 Grant Street

#### ABSTRACT OF DISCUSSION

DR. LAURA A. LANE, Minneapolis. I have failed to find any experimental evidence in the literature that a single trauma has caused cancer. On the other hand, there is extensive evidence that severe traumatized areas have not been followed by tumors. Furthermore, some observers have seen the size of a tumor diminish where trauma was applied to the tumors of animals. If trauma is a cause of sarcoma or carcinoma

the war injuries should have furnished proof by this time. Evidence here is lacking. Von Hausman has shown that not only has an increase not appeared following war injuries but new types have not appeared. The French Association for the Study of Cancer reported on the relationship of trauma and tumors in the light of experience gained since the war. All except Berard thought that trauma had nothing to do with the appearance of tumors. Research workers are finding, more frequently than ever before, definite metabolic changes in cancer patients, such as an increased  $pH$  or alkalinity of the blood. Carrel and others found that cancer cells proliferate much faster in culture mediums with high degrees of alkalinity. Many observers have found a high blood sugar, about 18 per cent above normal subjects. I have found only one point that might give weight to the trauma theory in this regard, namely, Ely found the blood sugar level high also in fracture cases. It is well to remember that the uveal tract often contains areas of nevi. These are known to develop malignant tendencies. I wish that Dr. Stieren had given some of the metabolic determinations and also what the blood grouping was in his patient. Malignant cases group largely in the AB or A group. In my study of 507 cases of sarcoma of the uveal tract, I found but sixty-six cases in which trauma was mentioned as an etiologic factor. The traumas, before diagnosis of a tumor, occurred from two weeks to one year in twenty-four cases, the remainder ranged from one to thirty years.

DR. FREDERICK H. VERHOEFF, Boston. Dr. Stieren has rightly pointed out that it is chiefly a legal question that he has brought up. If the case that he reports had come to trial and I was asked to testify, I should have testified only on the defense, I should have refused to testify as an expert witness on the other side. I rely on my own observations. In this case I should have instructed the lawyers for the defense to develop my testimony as follows. I should point out that although it was claimed that the sarcoma occurred at the site of the lesion, the pictures did not indicate this, they indicated that the sarcoma started at about the equator and that the wound was much farther forward. I should ask why sections were not made through the exact site of the injury to show just what had happened there. I should point out that every time one winks one injures the eyes and that in the morning the eyes are rubbed quite severely, yet sarcoma of the choroid is relatively very rare. I should hesitate to attach any importance to an injury that left no signs. The question is, What is reasonable or probable? Simply because it is possible that this sarcoma might have been due to trauma would be of no legal significance. The judge would not allow testimony based on possibilities only. I have made pathologic studies of many sarcomatous eyes, certainly over 300, and I don't recall a single one that showed any evidence of definite trauma. I have examined many eyes that have been severely injured, but I don't recall any one in which a sarcoma had developed. On this evidence alone it seems to be unreasonable to assume that a sarcoma of the choroid results from an injury. I can't deny that it is possible, but the question is, Is the evidence in the present case reasonable? I think it is entirely unreasonable and that the verdict should be for the defense.

DR. ADOLPH PFINGST, Louisville, Ky. While serving as assistant in the Schweigger clinic in Berlin in 1894 I had occasion to study a case of epibulbar neoplasm in which the development from the point of the lesion was quite evident, and which greatly resembled clinically the case just reported by Dr. Stieren. Virchow recognized the important part played by traumatism in the etiology of tumors. He found in the literature more than 800 cases of neoplasms in which there was a history of injury at the site of the growth. Since then an endless number of such cases have appeared in medical literature. The greater frequency of malignant growths in parts of the body most exposed to injury, such as the female breast, the mouth and the extremities, and the greater frequency of tumor development in individuals most exposed to trauma is further evidence of the influence of traumatism in the production of tumors. Yet when one takes into consideration the relatively infrequent development of new growths as compared to the great frequency with which the body is subjected to injuries, one cannot readily subscribe to the belief that trauma is the sole cause of their development. The rather

frequent occurrence of malignant growths of the uveal tract of the eye, which is surely not a very vulnerable structure, would also indicate that some contributory or predisposing factors must play a part in the development of neoplasms. Virchow maintained that the trauma serves only as the exciting cause and that a local predisposing anatomic anomaly, the result of congenital malformation or of a constitutional influence, plays the more important part, in fact, that such predisposing conditions are essential to their development. However, this theory as well as Billroth's theory of a hereditary predisposition and Cohnheim's hypothesis of the displacement of cells or groups of cells during fetal life and their later development, and also the more modern theories that living organisms or allergic processes are predisposing factors in the development of neoplasms, all fail of conclusive proof.

DR WILLIAM BENEDICT, Rochester, Minn. If one is concerned with the relationship between trauma and the development of malignant conditions about the eye, one must bear in mind that a careful history will inquire into the probability of an injury of such significance that it would be attributed as a cause of malignancy, particularly in compensation cases. Sometimes there is good evidence that the injury is of importance in the development of a malignant condition, probably not exactly at the site. I am not so sure that I would agree that the injury to an eye must occur at the exact spot where the malignant growth develops. There are by-effects of injury that must be taken into consideration. It is also of interest to consider the type of malignant growth that develops in connection with injury, at least an ascribed injury so far as the subject is concerned. I have gone over my statistics and have looked up that relationship between the various types of tumors and the claim made by the patient that was considered to be significant of injury. The incidence of injury in 1,439 cases of tumors of the eye and orbit at the Mayo Clinic was as follows:

Type of Tumor	History of		
	Cases	Injury	Per Cent
Epithelioma primary cases	510	58	11.37
Epithelioma secondary cases	182	20	10.98
Melano epithelioma	126	9	7.14
Intra ocular	87		
*Orbital	20		
I eyelid and caruncle	13		
Conjunctiva and limbus	10		
Sarcoma	75	13	17.33
Carcinoma	33	1	3.03
Intra ocular	20		
Extra ocular	31		
Glioma	55	2	3.63
Angioma	109	5	4.58
Cysts	152	1	0.65
Osteoma	22	4	18.18
Endothelioma	16	1	6.25
Fibroma and fibroneuroma	15	1	6.66
Granuloma	15	2	13.33
Tuberculoma	4	1	25.00
Papilloma	38	0	
Miscellaneous tumors	87	1	1.14
Total	1,439	119	Av 8.26

\* In fifteen cases or 75 per cent of this group previous enucleation had been done for primary intra ocular melano-epithelioma elsewhere also three out of the four with injury.

These statistics mean only this: that injury is claimed in certain types of tumor more often than in others. Neuroblastomas occur in children when one would not expect to find as much history of injury as one would in older persons in whom epitheliomas develop. The types of tumors that develop in later years have the largest percentage of history of injury, so, after all, the relationship may be purely incidental and have little significance as far as cause and effect are concerned.

DR EDWARD STIEREN, Pittsburgh. In Pennsylvania the compensation law provides that in a general injury the case can be opened within fifty weeks, but in eye injuries the case can be opened 500 weeks (almost ten years) later. As my patient might have gone to court nine years after the injury, he was entitled to compensation and would no doubt have received it for the loss of an eye. I admire Dr. Verhoeff's stand. I think that personal experience when giving expert testimony, means more than statistics but unfortunately, juries

and compensation referees do not reason that way. If I were to appear against Dr. Verhoeff in this case and he should take the negative stand, I would need merely to quote statistics, not only of ophthalmologists but of general surgeons, and I am sure that the jury or the compensation referee would give more weight to that than to the opinion of a single man. As Segond says, all statistics are merely empiricisms under mathematical disguise, and these well studied out cases will increase one's opinion on the matter more than all the statistics. I want to apologize to Dr. Pfingst for not including his case in the report, but I went back only thirty years, reading hundred of reports, and only in these seven cases was trauma mentioned as a factor. Dr. Lane and Dr. Verhoeff both mentioned the fact that probably this man had reached a cancerous age and was going to have cancer anyway. Holloway's patient was a youth, aged 21, and Nitsch's a child, aged 7 years, so one would think that the trauma had a causal relation in these instances.

## UNDESCENDED TESTES IN MAN AND RHESUS MONKEYS

TREATED WITH THE ANTERIOR PITUITARY-LIKE PRINCIPLE FROM THE URINE OF PREGNANCY

S B D ABERLE, PH D, MD

AND

RALPH H JENKINS, MD

NEW HAVEN, CONN

Cases of cryptorchidism present a difficult clinical problem. There have been two methods of relief. One is to wait for the testes to descend spontaneously. The other is to place the testes in the scrotum surgically. Recently a third possibility has presented itself, namely, the administration of the anterior pituitary-like principle from the urine of pregnancy.

The practice of waiting to see whether the testes will descend naturally has obvious disadvantages. A recent article by Drake<sup>1</sup> reported thirty-five cases of undescended testes in boys between the ages of 9 and 19 years. Twenty-three of the thirty-five boys showed a spontaneous descent between the ages of 10 and 16 years. The greatest number descended at the time of puberty. In twelve boys the testes did not descend. Besides the possibility of complications to the undescended gland, such as trauma, pain, hernia, torsion of the cord, hydrocele and neurologic manifestations, there is the possibility of abnormal development.

Moore<sup>2</sup> has established the fact that testes in most mammals cannot develop normally except in the scrotum. He has shown that the germinal epithelium of testes placed in the abdomen undergoes degeneration. The interstitial cells seem to be unaffected. For man the case seems to be similar.

Wangensteen's<sup>3</sup> studies in dogs and man show that the undescended testis owes its imperfection to its abdominal position. He summarizes the literature regarding the approximate age at which the undescended gland in man shows degenerative changes. He did not find many cases of prepubescent undescended

From the Department of Surgery, Yale University School of Medicine. This investigation was partially subsidized by a grant from the National Research Council Committee for Research in Problems of Sex. Read before the combined meeting of the New York, Philadelphia and New England branches of the American Urological Association, New Haven, Conn., April 21, 1934.

3 Wangenstein, O. H. The Undescended Testis. Arch. Surg. 14:663 (March) 1927.

testes which have been studied histologically. From the evidence available he concludes that undescended testes in man remain normal until puberty. On the other hand, Cooper<sup>4</sup> has found in his large series that undescended testes in boys over 2½ or 3 years of age almost always show anatomic defects. He found a reduction in the number and size of the tubules and an increase in the intervening stroma. The tubular cells, he says, were normal in appearance although less in number. The further the preadolescent testis had descended in its normal route, the more closely did it correspond histologically to the scrotal gland of the same age. The anatomic changes also increased with age. These investigators agree that, in the adult, retained testes are usually aspermatic. Thus the available evidence seems to indicate that the sooner the undescended gland can be placed in the scrotum, the better are its chances of being a normal functioning organ.

The results of surgery have not been as gratifying as might be hoped. A summary of recent literature shows that operations do not always result in bringing the testes to the normal low scrotal position. In a series of more than 500 operations reported by Burdeck and Coley,<sup>5</sup> satisfactory results were obtained in about 50 per cent of the cases. By satisfactory results is meant

is extracted from the urine of pregnant women. Engle<sup>10</sup> and Moore<sup>11</sup> have shown that in the male rat injections of anterior pituitary-like principle from the urine of pregnancy cause an increase in the weight of the genital tract. In 1932 Engle reported that the testes of the immature rhesus monkey can be made to descend into the scrotum by injections of this gonadotropic factor. In the prepubescent rhesus monkey the testes are normally situated above the scrotum. At about 6 years of age they descend into the scrotum. Schapiro<sup>12</sup> reported thirteen cases of cryptorchidism in man in which the injection of anterior pituitary-like principle caused greater motility of the testes in all cases. Goldman and Stern<sup>13</sup> reported that two boys with undescended testes were treated successfully by injections of this principle. Details are not given in either paper as to the total dosage of the hormone and other endocrine substances given, or as to the final position of the testes in the scrotum.

#### EXPERIMENTAL DATA

Six monkeys were used in this experiment. One was killed as a control. The left testis in the five remaining animals could be moved to a position outside of the external inguinal ring. An incision was made over the gland at this point and the testis removed.

TABLE 1—The Effect of Anterior Pituitary-Like Substance on the Undescended Testes of Rhesus Monkeys

Monkey	Body Weight Gm	Total Dosage Rat Units*	Position of Undescended Testes	Size of Gland				Results
				Before Injections		After Injections		
				Measurement Left Cm †	Weight Left Gm	Measurement Right, Cm †	Weight Right Gm	
200	1 675	2 575	Inguinal canal	0 60 by 0 90	0 201	0 80 by 1 10	0 321	Testis above scrotum
201	1 020	1 220	Inguinal canal	0 55 by 0 90	0 139		0 235	Testis in middle of scrotum
202	1 720	Control	Inguinal canal	0 54 by 0 95	0 123			
203	1 710	2 575	Inguinal canal	0 60 by 0 90	0 169	0 85 by 1 10	0 326	Testis at base of external inguinal ring
204	2 200	2 575	Inguinal canal	0 60 by 1 10	0 254	1 00 by 1 40	0 648	Testis in middle of scrotum
205	1 730	2 575	Inguinal canal	0 60 by 1 00	0 198	0 80 by 1 20	0 543	Testis in lower part of scrotum

\* Each cubic centimeter of the fluid was standardized to contain 250 rat units of the gonadotropic factor. The animals received their injections five times a week. 0.3 cc was given for eleven days. 0.4 cc for four days. At this time monkey 201 was killed. The other animals received one more injection of 0.4 cc. then injections were stopped for a week. They commenced again at 0.4 cc a day for five days. 1.0 cc for three days.

† The measurements are width by length.

the presence of operated testes in the lower or upper part of the scrotum. Eisenstaedt<sup>6</sup> reported the results of operations in ten patients, of these four had the testes in the midscrotal position and six had the testes low in the scrotum. Goetsch<sup>7</sup> reported thirty-two cases. In seven the testis was in the lower part of the scrotum, in two in the middle of the scrotum, in five high in the scrotum, and in one the testis was missing. For the remainder, data are wanting. Cabot<sup>8</sup> reported seventeen cases that he was able to follow. Among these the testes were found in the normal scrotal position in ten instances and in the upper part of the scrotum in seven instances, in none were they found higher up.

The third method of treating undescended testes is by the injection of a hormone, and this method forms the basis for the present report.<sup>9</sup> The hormone used

The size and weight of the gland before and after injections, the amount of anterior pituitary-like principle administered, and the result of the injections on the remaining testis are tabulated in table 1. The first noticeable effect of the anterior pituitary-like factor was an increase in the size and fullness of the scrotum. It can be seen from table 1 that after the administration of this substance the right testis approximately doubled in weight and increased noticeably in size. In only one instance (monkey 205), however, did the testis descend to the lower part of the scrotum.

When the animals were killed a careful dissection was made to determine in the remaining four animals the reason that the testis did not descend. In all these

instances the fascia surrounding the vas deferens and spermatic vessels was short. When the fascia was removed the vas deferens and vessels were long enough in three instances to allow the testis to be placed in the lower part of the scrotum. In monkey 200 the vas deferens was short, it had to be cut to allow the testis to be placed in the normal position.

Slight hypertrophy of the seminal vesicles was found in two instances and a marked hypertrophy in animal 205. In this animal the seminal vesicles measured 3.2 cm in length as compared to 1.8 cm in the control. The prostate was correspondingly increased in size, measuring 2.0 cm in length as compared to 0.9 cm in the control. The penis in this animal was also hypertrophied. Histologically all the testes showed an increase in the diameter of the tubules and a corresponding increase in the interstitial tissue.

Identical dosages of anterior pituitary-like substance caused different reactions. All the animals were about the same weight, were kept in the same room and were fed similar food, yet in only one did the seminal vesicle, penis and prostate hypertrophy to a marked degree.

enlargement, the penis was not increased in size, and no change in secondary sex characteristics was observed.

Case 3 showed a marked reaction after the first injection of 0.4 cc of the gonadotropic principle. A few hours after the injection the patient's foster mother reported a rise in temperature, fretfulness and gastro-intestinal upset. The injection was reduced to 0.2 cc for the next dose, and then increased 0.1 cc each succeeding dose until 0.4 cc had again been reached. The patient was given injections three times a week for a period of three weeks. The treatment was then discontinued for nineteen days because of chickenpox. It was started again with 0.2 cc and increased to 0.4 cc for five injections. Then 0.5 cc was given two times, 0.6 cc two times, 0.7 cc two times and 0.8 cc three times. The boy had a total of 2,750 rat units, a much larger total dose than patient 5 of the same age.

In case 3 the left testis, which, being in the normal position, could be measured, increased markedly in size, and the scrotum increased in size and fullness (fig. 1). The penis was normal in size for the patient's age at the beginning of the experiment and was noticeably

TABLE 2—The Effect of Anterior Pituitary Like Substance on the Undescended Testes of Boys

Case	Age in Years	General Appearance*	Total Dosage Rat Units†	Position of Undescended Testes	Measurement of Gland in Cm				Results
					Before Injections		After Injections		
					Left	Right	Left	Right	
1	8	Underweight normal height suffering from an infected ear	1.0	Left in inguinal canal		0.8 by 1.7			Discontinued reaction too severe
2	13	Underweight normal height	1 000	Right in abdomen left in inguinal canal					No change in position of testis
3	3	Bright alert normal height overweight	2 700	Right in inguinal canal	0.7 by 1.5		1.6 by 2.8		No change in position of testis
4	11	Bright alert normal height overweight	4 525	Right in inguinal canal	1.3 by 2.1		1.5 by 3.4	1.6 by 4.0	Right testis in mid-scrotal position
5	8	Taller and heavier than usual for his age	1 700	Right in inguinal canal	0.6 by 1.6		1.3 by 2.2	1.3 by 2.4	Right testis in lower part of scrotum

\* The measurements of heights and weights were compared to the Baldwin, Wood and Woodbury weight height tables.

† Each cubic centimeter of liquid was standardized to contain 250 rat units of the substance.

‡ The width and length of the glands were measured. No attempt was made to measure anteroposterior thickness. The figures can be taken only as an approximation since it is almost impossible to obtain accurate measurements of soft tissue.

In two animals the testis descended to a short distance beyond the external inguinal ring but did not enter the scrotum, in two it descended to the midscrotal position, and in only one did the testis reach the low scrotal position (monkey 205).

Table 2 gives a summary history of the boys treated with anterior pituitary-like principle from the urine of pregnancy. The injections were given intramuscularly. In case 1, the treatment had to be discontinued after two injections because of the marked febrile reaction. The patient's temperature rose to 102 F and remained there for three days.

In case 2 the testes could not be measured because they were in the abdomen and in the inguinal canal. This patient was given 0.4 cc, or 100 rat units, of the anterior pituitary-like principle three times a week. He did not come regularly for treatment but received a total of 1,900 rat units. The testes appeared to increase in size as the treatment progressed and became more freely movable but could not be made to descend, even when force was exerted. The patient complained after each injection of nausea and vomiting and of pain in the inguinal region. After the patient had received 7.6 cc of this substance the scrotum showed some

large for his age when the photograph was taken. When he was examined rectally after having received a total of 2,750 rat units of anterior pituitary-like principle, the prostate felt tense. This is what one would expect. With a marked increase in the size of the scrotum, testes and penis, monkey 205 showed an increase in the prostate and seminal vesicles. No growth of secondary sex characteristics was seen. The right testis did not descend. It became more movable but could not be pushed beyond the point at which it was at the beginning of the experiment.

In case 4 the patient received 2,525 rat units of the gonadotropic factor and the right testis descended to the midscrotal position. The left testis was in the normal scrotal position. The right testis would slip back into the inguinal canal on exertion. Injections were continued until the patient received a total of 4,525 rat units. The substance was given three times a week. For one week 0.4 cc at each injection was given, for four weeks 0.5 cc was given at each injection, one injection each of 0.6 cc, 0.7 cc and 0.8 cc three times a week for four weeks was given. At this time the testis remained stationary in the midscrotal position. Figure 2A shows the external genitalia before injection.

tion, and figure 2B the scrotum containing the right testis. In spite of the additional amount of anterior pituitary-like principle the testis did not descend farther. The patient at no time showed any general reaction to the injections. The scrotum was enlarged, but no increase in the size of the penis was observed. Enlargement of the prostate could not be discovered on rectal examinations. The testes became larger. During the treatment the hair on the patient's upper lip increased somewhat in density and a slight amount of pubic hair appeared. No other changes in the secondary sex characteristics were observed.

Case 5 showed a definite increase in the size of the scrotum and left testis. He received seventeen injections of 0.4 cc each for a period of seven weeks. The right testis descended after the boy had received 1,700 rat units of the anterior pituitary-like factor, reaching the lower scrotal position. Figures 2C and 2D show the external genitalia before and after treatment. No increase in the size of the penis was observed, and no secondary sex characteristics appeared. Enlargement of the prostate was not noted on rectal examination.

The patient showed on two occasions temporary reactions to the anterior pituitary-like substance. The temperature rose to 101 F for several hours. Otherwise the temperature, which was taken daily throughout the experiment, was normal.

Fig. 1 (case 3)—A boy, aged 3 years, after having received 2,750 rat units of anterior pituitary-like substance from the urine of pregnancy. The external genitalia can be seen to be markedly larger than is normal for that age. Prior to the injections the external genitalia were normal in size.

#### COMMENT

Anterior pituitary-like principle from the urine of pregnancy caused the complete descent of the testes in one child receiving 1,700 rat units, caused the testis to assume the midscrotal position in one patient receiving 4,525 rat units, and did not cause any descent of the testes in two patients receiving 1,900 and 2,750 rat units, respectively. The experimental results obtained in monkeys can be compared only partially to those obtained in man. In man the presence of undescended testes is abnormal, while in immature rhesus monkeys it is normal. In monkeys the anterior pituitary-like principle caused the testis to assume the midscrotal position in four out of five cases and caused complete descent in one instance. This is not in accord with the cases reported by Engle,<sup>10b</sup> who reported complete descent in eight out of ten monkeys. In the two instances in which complete descent did not

occur he says that one was due to sequelae following operation, the other to an increase of the tissue content of the scrotum.

In the group reported here, the shortness of the fascia surrounding the vas deferens and spermatic vessels was

Fig. 2 (case 4)—A boy, aged 11 years. A, external genitalia before injections; the right testis was in the inguinal canal. B, external genitalia following the injection of 4,525 rat units of anterior pituitary-like principle; the right testis can be seen in the midscrotal position. Case 5, a boy aged 3 years. C, before injections of the gonadotropic factor; the right testis was in the inguinal canal. D, after having received 1,700 rat units of the substance, the right testis can be seen to occupy a position low in the scrotum.

period, which is the time that elapsed in this experiment. The histologic picture in the monkeys' testes resembled that found by Engle<sup>10b</sup> for the rats and monkeys, namely, an increase in the tubules and interstitial tissue. The seminal vesicles and prostate of Engle's monkeys were greatly enlarged. This enlargement is reported by Moore<sup>11</sup> to be effected through the testes, since no enlargement is obtained when anterior pituitary-like substance is injected into spayed animals. One would therefore expect to find an enlargement in the seminal vesicles and prostate of boys when the testes were seen to increase in size. However, rectal examinations disclosed only one case of definite enlargement (case 3). In this case also the greatest increase in size of the penis and scrotum was found. The fact that no enlargement of prostate and seminal vesicles was found in the three other cases was probably due to the difficulty of palpating a slight enlargement.

Goldman and Stern<sup>12</sup> report testicular enlargement in boys 12 and 15 years of age. They also report a development of the secondary sex characteristics where we noted it in only one patient. This was the patient 11 years of age. No increase in sex characteristics was noted in two patients 3 years of age.

The amount of the material given does not bear a direct relation to the effect on the descent of the testes.

Patient 3 received 2,750 rat units. This dosage had a marked effect, as could be seen from the increase in size of the penis, left testis and scrotum, yet the right testis did not get below the external inguinal ring. Patient 5 had 1,700 rat units of the substance, and the testes moved all the way to the base of the scrotum.

The possibility of an outside mechanical factor obstructing the descent of the testes cannot be eliminated. However, in the case of the monkeys the testes did not assume a lower scrotal position, and here on dissection there was found no external mechanical obstruction. The age, the duration of the injections, the nutrition and possibly the condition of the other endocrine glands may have something to do with the effectiveness of the injected hormone. Borst<sup>14</sup> has shown that, in rats, anterior pituitary-like substance in equal doses has a marked effect on the genital organs of the immature rat, less effect on the rat just past puberty, and no effect on old animals. One of us<sup>15</sup> has shown that a hormone which can produce definite vaginal changes in normal animals is without any effect in rats suffering from avitaminosis A. Selye and his associates<sup>16</sup> have shown a loss of sensitivity to anterior pituitary-like substance in rats after several weeks of injection. Collip and his associates<sup>17</sup> have demonstrated histologic changes in the ovaries and hypophyses of white rats given continuous injections of hypophyseal extracts. There may be many reasons, yet unknown, why a hormone effective in one organism is ineffective in another.

According to tables of Reich given by Wangenstein<sup>3</sup> for the normal size of the testes, in our subjects the testes were normal in size for the age of the individual at the beginning of the experiment. Those in the boys of 3 years of age increased in size to that found in children at puberty, and those in the boy of 11 increased in size to those found at from 16 to 17 years of age. Just what effect this will have on their subsequent development cannot be predicted.

#### CONCLUSIONS

Anterior pituitary-like principle from the urine of pregnancy caused the testes to descend in two out of four boys receiving injections. In only one instance was the descent complete. The substance caused hypertrophy of the scrotum and testes and in one instance a growth of the penis.

In immature monkeys (*Macaca mulatta*) with unilateral orchidectomy, this hormone caused complete descent of the testis in one animal and partial descent of the testes in four. In these four animals the fascia surrounding the vas deferens and spermatic vessels was too short to allow the testes to reach the lower part of the scrotum.

The failure of the treatment may have been due to an incorrect amount of hormone, to age, to nutrition, or to some factor related to the activity of the other endocrine glands. In man a possible external mechanical obstruction and developmental irregularities must be considered.

Microscopic examination of the testes of the injected monkeys showed marked tubular enlargement, a corre-

sponding increase in interstitial material, but no mature sperm.

Identical amounts of the anterior pituitary-like factor caused various degrees of hypertrophy in the prostate, seminal vesicles and testes of immature monkeys. The total dosage of the principle administered is not in direct proportion to the distance that the testes descend either in man or in monkeys.

## THE EFFECTS OF TOBACCO ON THE PERIPHERAL VASCULAR SYSTEM

### FURTHER STUDIES

IRVING S. WRIGHT, M.D.

AND

DEAN MOFFAT, M.D.

NEW YORK

On the basis of clinical and experimental observations, it has been recorded by many authors<sup>1</sup> that the use of tobacco produces definite effects on the vascular system, which are particularly important in certain disease conditions, such as thrombo-angitis obliterans and angina pectoris. In spite of this widely recognized association, the available evidence has tended to show that the smoking of tobacco must be looked on as an aggravating rather than an etiologic factor.

Following the work of Maddock and Coller,<sup>2</sup> experiments have been reported by Barker,<sup>3</sup> Johnson<sup>4</sup> and Wright,<sup>5</sup> proving that the smoking of cigarettes will produce in the great majority of normal individuals, under certain conditions, a marked change in the surface temperature of the extremities. This can be measured at the tips of the fingers and toes. We noted that in many instances slowing and even stoppage of the blood flow occurred in the capillaries of the nail fold during the smoking of a cigarette.<sup>5</sup>

Maddock and Coller<sup>2</sup> later demonstrated that drops in the surface temperature were accompanied by rises in the pulse rate and in the blood pressure. These early studies have left many problems unsolved and have suggested new questions. The experiments here reported were undertaken with the object of answering certain of these.

## TECHNIC

The tests were made with the patients in a sitting position, with the hands at the level of the heart. The surface temperature readings were either made on a recording potentiometer or recorded every minute from a nonrecording potentiometer. The observation of the capillaries was continuous during each experiment. In some instances the nail folds of the fingers of the left hand were used for capillary microscopy, while the fingers of the right hand were utilized for readings of the surface temperature. In other instances the observations on the capillaries and surface temperature readings were made from the fingers of the same hand. The forehead temperatures were studied in a group of cases. The temperature of the room was carefully controlled, the average variation during the experiment being between 2 and 3 degrees Fahrenheit. In each instance a control period was studied. It was found that when an individual comes in from outdoors, or even from elsewhere in the same building, the surface temperature tends to fluctuate widely at first. The fluctuations become less marked, and the experiments were not begun until the fluctuations were less than 2 degrees. At times this necessitated the making of observations for more than an hour before smoking was started. The observations of the capillaries and the

Chart 1—Surface temperature curve at the finger tips of a subject produced by the smoking of a single standard cigarette (Cigarette III patient G W Dec 22 1933) A fourth terminal phalanx left hand B room temperature

readings of the surface temperature were made according to a previously reported technic.

The cigarette was suspended on a slender reed, at the level of the subject's mouth, permitting ease of smoking. The individual was urged to smoke at his normal rate, although it is probable, at least in certain instances, that there was an increase in both the rate and the depth of inhalation during the experiment. Eleven brands of commonly used cigarettes were utilized, including two demotomized brands and one mentholated brand.

The subjects were not blindfolded, but the names of the cigarettes were carefully covered so that the subjects were not aware of them. The temperature readings were concealed from the subjects until the completion of each test. Similar studies of the effects of cigars have not yet been made. The effect of smoking a pipe is being studied now.

The "filter-paper" cigarettes were prepared as follows. Ashless filter paper was washed in alcohol and ether to remove all fat. After being dried in an oven it was shredded, to simulate tobacco. Two standard white cigarette papers were shredded and mixed with two filter

Chart 2—Similar reaction at the finger tips with a stable forehead temperature. Compare with chart 3. (Cigarette III patient K I Oct 27, 1933) Solid line temperature of terminal phalanx of fourth finger, left hand, broken line temperature of the forehead

papers. The mixture was formed into a cigarette in a cigarette rolling machine, a third cigarette paper being used. It was then humidized. The technic of smoking the filter paper cigarettes was identical with that employed for the tobacco cigarettes.

After the conclusion of each period of smoking, the subject was kept in the same position until the temperature had become reestablished at the normal level. At times, this necessitated continuous observation over several hours and, in rare cases, the experiment had to be discontinued before the normal level of the temperature could be established.

## EXPERIMENTS

The peripheral vascular reactions to the smoking of cigarettes have been studied in more than 100 experiments at the New York Post-Graduate Hospital. The first thirty-four studies were reported by Johnson.

The present report is based on ninety experiments, in which a somewhat more elaborate technic was used and the effects of a larger number of brands of cigarettes were studied. The subjects were confirmed smokers and were in an average state of health. Four groups of cigarettes were utilized. For each test, only one cigarette or less was used.

A. The first group, known as "standard brands," was made up of eight makes of cigarettes, including the better

known brands containing American and Egyptian tobaccos in varying proportions. The study of this group demonstrated the following facts:

1 Under controlled conditions, practically 100 per cent of subjects who inhale show a definite drop in the surface temperature when taken at the finger tips. The change in the temperature may not occur with the smoking of every cigarette,

Chart 3—Lack of effect of a cigarette of the same brand on the same individual at a different time. Compare with chart 2 (Cigarette III patient K I Nov 1 1933). Solid line, temperature of the terminal phalanx of the left fourth finger; broken line, temperature of the forehead.

no effect on the degree of the drop in the temperature, some of the most profound drops being seen in the heaviest smokers.

6 Smoking without inhaling resulted in decreased effects on the surface temperature at the finger tips.

7 There was no appreciable effect on the forehead temperature during any of these experiments. The same observation has been made previously concerning the surface temperature at the waist.

8 Under these conditions, in sixteen tests the subjects complained of mild symptoms of tobacco poisoning, such as tingling of the fingers and slight vertigo, and in seven instances severe symptoms developed, including nausea with vomiting, marked vertigo, cold sweats, pallor and even profound syncope. These symptoms, typical of those occurring with the first use of tobacco, were noted in experienced smokers the number of years of smoking of those in whom severe reactions were noted being ten years, five years, five years, three years, seven years, thirteen years and five years. The average consumption of these subjects varied between fifteen and thirty cigarettes a day without marked symptoms. With certain cigarettes especially the first one smoked each day most of the subjects felt effects such as light-headedness, dizziness and nausea.

9 In seventeen of forty (42.5 per cent) tests in which observations were made the blood flow through the capillaries of the nail fold was definitely observed to slow during the smoking of a cigarette. Allowance was made for the average change in rate of flow. In the remainder no change could be noted. There did not seem to be a definite relationship between the number of degrees of the drop in temperature and the degree of slowing of the capillary blood flow. In five of the seven subjects who experienced severe reactions, the rate of flow was definitely slowed. In several instances stoppage was noted. The sixth case showed great variability in rate of flow, and the

seventh could not be observed, because of the severity of the reaction.

10 There was no appreciable difference in the effects produced by the various brands of "standard" cigarettes. One individual did appear to be definitely more sensitive to one standard brand than to any other. This was confirmed with repeated tests.

B The second group was composed of two brands from the so-called denicotinized cigarette classification. No marked difference in reactions could be noted between the two brands used from this class of cigarette. In a series of ten studies the average drop in surface temperature at the tips of the fingers was 4.8 degrees Fahrenheit, or 0.5 degree less than the average for the "standard brands." In view of the few subjects tested in this series, the variation is negligible. Individual studies, however, are very illuminating. The same subject on the same day showed a 12.1 degree drop resulting from the use of a "standard brand" and, after returning to normal, a 12.8 degree drop resulted from the use of a "denicotinized" cigarette.

Another subject showed, Jan 9, 1934, a temperature drop of 8 degrees with the use of a "standard brand" and on January 31 a drop of 9.5 degrees Fahrenheit with the use of a "denicotinized" brand. On the other hand, there were instances in which the drop following the use of "standard brands" was more marked than that following the use of "denicotinized

Chart 4—Profound drop in temperature with development of toxic symptoms noted in a moderately heavy smoker of seven years experience (Cigarette IV patient C D). A fourth terminal phalanx left hand; B room temperature; C one half cigarette; nausea and syncope forced discontinuance of experiment; D observations continued.

D The fourth group consisted of the "ashless filter paper cigarette," prepared as already described. Ten tests were made in which these cigarettes were used. No appreciable effects on the surface temperature were noted in any instance. Aside from sensations of burning and dryness in the throat, no symptoms were com-

brands. The changes in the capillary blood flow and the symptomatology were not different from those encountered in group 1. There were, however, a few cases of syncope in this small series.

C The third group was made up of a single brand of "mentholated" cigarette. Ten tests were run with this brand. A drop of 11 degrees Fahrenheit in one individual and of 9 degrees Fahrenheit in another clearly demonstrated that this process did not affect the vasoconstricting properties of the tobacco smoke. The change in the capillary blood flow and the symptoms were the same as those noted in groups 1 and 2.

plained of in this series. No abnormal changes in the rate of the capillary blood flow were noted.

#### SKIN TESTS

With the cooperation of Dr Marion Sulzberger, a small series of cases have been studied in an attempt to determine whether our test could be correlated with the intradermal skin tests for tobacco and nicotine hypersensitivity presented by Harkavy and his co-workers<sup>8</sup> and by Sulzberger.<sup>9</sup>

At the time that the skin tests were performed by Dr Sulzberger, he did not know the degree of reaction produced by smoking according to our studies. The preparation of the extracts used was previously described by Sulzberger.<sup>9</sup>

While it is too early to pronounce final judgment on the problem from the point of view of statistics, certain observations are of considerable interest.

The first four individuals studied showed the following reactions:

Patient R, who showed a drop of 9.6 degrees F in the surface temperature at the finger tips with the development of moderate symptomatology was negative to the skin test for nicotine but showed reactions of three to four plus to the skin test for tobacco.

Patient B, who showed a drop of 9.1 degrees F in the surface temperature gave a questionable positive reaction to nicotine and a negative reaction to tobacco extract.

Patient W, who showed a 10.8 degree F drop in surface temperature was negative to both nicotine and tobacco extract.

Patient M, who showed no drop in temperature during tests with three cigarettes gave a negative reaction to nicotine and showed a one to two plus reaction to tobacco.

Other subjects have shown a close relationship between surface temperature reactions and skin tests to tobacco and nicotine. The study will be continued and the result reported at a later date.

#### COMMENT

As a result of previous observations and the studies here reported it becomes obvious that certain variable factors play a large part in determining the degree of physiologic reaction resulting from smoking. One is the sensitivity of the individual to the smoke at the particular moment of smoking. We are not referring to allergic sensitiveness since that is a moot point in view of our tests, but rather to the physical condition, which is affected by physical and nervous fatigue, the emo-

tional state, the inherited and acquired neurovascular balance, preceding food, the time and amount of tobacco consumed shortly before, existing diseases, and other factors not understood. In view of the fact that experienced and heavy smokers showed some of the most profound temperature and symptomatic reactions under controlled conditions, we are forced to conclude that, at least in many individuals, habitual smoking does not result in the development of an immunity to the toxins of cigaret smoke. It would seem rather that experience teaches one often subconsciously to control one's smoking so that the effects are kept at a submanifest point. This may involve what is termed desire. To be concrete, one does not take another puff from a cigaret if certain effects of the one preceding are manifest. Similarly, a second cigaret is not smoked until the effects of the preceding one have worn off. Our experiments have shown that the length of time necessary for these effects to wear off varies greatly in different individuals and even in the same individual at different times.

Two elements are prominent in the desire for the "next" smoke: the first being the wish for the soothing quieting effect of the smoke, which increases with the cessation of the effects of the preceding cigaret, and the second being the nervous desire to do something with one's hands. It is usually noticed that the most

Chart 5—Effect of smoking a denicotinized cigaret on the finger tip surface temperature. Compare with chart 1 showing the effect of a standard brand of the same individual (Cigaret VII patient G W Dec 22, 1933) A fourth terminal phalanx left hand B room temperature

Chart 6—Effect of smoking a mentholated cigaret on the surface temperature at the finger tips (Cigaret VIII, patient M W)

immoderate smokers who use from forty to sixty cigarettes a day, actually smoke less than half of each cigaret, indicating that the nervous habit plays a large part and that the toxic effects are quickly felt. Thus the question arises why such severe reactions developed in these experienced smokers during the experiments when ordinarily they have only minor or no symptoms.

<sup>8</sup> Harkavy J, Hebal S and Silbert Samuel. Tobacco Sensitivity in Thrombo-Angitis Obliterans. *Proc Soc Exper Biol & Med* 30: 104 (Oct) 1932. Harkavy J. Tobacco Sensitivity in Angina Pectoris and Coronary Artery Disease. *ibid* 30: 683 (Feb) 1933.  
<sup>9</sup> Sulzberger M B. *J Immunol* 24: 85 (Jan) 265 (March) 1933.  
Sulzberger M B and Feit Emanuel. *ibid* 425 (May) 1933. Recent Immunologic Experiments in Tobacco Hypersensitivity. *Bull New York Acad Med* 9: 294 (May) 1933.

We believe that a purely psychologic explanation can be discounted, for several reasons

1 The reactions were severe, with a profound drop in the surface temperature, marked slowing to stoppage of the blood flow, cold sweat, nausea, vomiting, fainting and, in several instances, clonic convulsions during the periods of unconsciousness

2 In no instance did these subjects anticipate any reaction whatever. All of them approached the experiment with the spirit of interest and enjoyment. Several of them were very familiar with the laboratory and equipment and could be considered as objective, scientific workers

3 The equipment was not formidable, and no discomfort or pain was involved in the experiment

Careful questioning has inclined us to the view that, although we suggested that the rate of smoking be normal, the individual continued to smoke steadily after the toxic symptoms had become manifest and until a severe reaction was obtained, whereas ordinarily the cigaret would have been laid aside or at least no further inhalations taken when the symptoms reached the manifest level. In other words, the subjects continued to smoke after the desire to do so had become oversaturated.

Whether the development of desire and the effects have a definite relationship to the changes in the blood sugar recently noted by Haggard and Greenberg<sup>10</sup> remains to be established by further studies.

The other great factor, or group of factors, lies in the preparation of the cigaret. We are not yet sure which constituent or constituents can be said to be responsible for the effects of smoking. The following must be considered: carbon monoxide, nicotine, ammonia, pyridine and pyridine derivative, cyanides and sulphocyanides, arsenic and nitrites, which are contained in cigaret papers to facilitate burning.

Carbon monoxide seems to have been eliminated as a causative factor by the following experiments. Maddock and Coiler<sup>9</sup> did not obtain a drop in temperature or rise in pulse or blood pressure with the use of cubebs. Barker<sup>11</sup> obtained no effects from the smoking of cigaret papers in a pipe. This, incidentally, seems to eliminate the nitrites as possible offenders. In experiments here reported we noted no effect from the use of ashless filter paper cigarettes which reduced, on burning, to carbon monoxide and oxygen. The nitrites in the cigaret papers were also eliminated by these experiments, because each of the cigarettes contained three papers.

Nicotine has long been considered the most important factor in the causation of effects from cigarettes. The vital consideration is not how much of this poison is in the tobacco but how much is actually absorbed through the mucous membranes and alveolar walls into the blood stream. The tobacco itself varies widely in nicotine content. For example, the average nicotine content of various tobacco is as follows: Havana tobacco, 1.5 per cent, Maryland tobacco, 2 per cent, Virginia tobacco, 6 per cent, Kentucky tobacco, 8 per cent.<sup>12</sup> The amount of nicotine and other products in the inhaled smoke is influenced greatly by, first and most important, the amount of moisture present, and also the tightness of packing, the length of the cigaret and the rate of smoking. The drier the tobacco, the greater the destruction of nicotine. Dixon<sup>13</sup> states that the water content of the tobacco is more harmful to the smoker than the original nicotine content.

Recent work<sup>6</sup> in which parallel results in the effect on the surface temperature, pulse and blood pressure were obtained by the intravenous injection of 1 mg of nicotine seems to point strongly to nicotine as the offending factor. Insufficient work has been done to determine the importance of the other constituents of the cigaret in the causation of symptoms. The localization of the reactions to the extremities presents an interesting field for speculation as to the mechanism involved.

The areas involved and the type of reactions, both objective and subjective, would incline one to believe that the toxins act on the central nervous system, involving certain cortical areas and the sympathetic trunks controlling the vascular supply to the parts affected rather than on the walls of the blood vessels directly.

We are familiar with certain other sharply localized symptoms associated with smoking, such as anginal attacks in patients with and without demonstrable organic coronary changes, and vertigo. These may well be explained by similar vascular spasm affecting the terminal vessels locally and producing a secondary ischemia. We have had one instance in which a subject who, during several previous experiments showed a bilateral drop in the temperature of her fingers, on one occasion showed a unilateral drop of 8.5 degrees F, the other hand remaining unaffected.

The fact that there was no appreciable difference in the average effect noted between the "standard" and the "demotized" cigarettes and that profound drops in temperature could be elicited by the smoking of the latter brands was of interest. The average and individual nicotine content of the two brands used was less than 40 per cent of the average for the "standard" brands used,<sup>13</sup> according to figures published in 1929. This is further evidence that the nicotine content does not control completely the amount of absorption and that perhaps other factors contribute to these effects.

We did not anticipate that the process of "mentholating" a cigaret would produce any effect on the general physiologic action of the tobacco smoke. This was demonstrated to be correct.

As previously stated, we are not prepared to draw definite conclusions as to the correlation of the skin tests with the circulatory tests. The evidence, however, would tend to show that there was no direct relationship between them, and that these effects on the circulation cannot be explained on an allergic basis. Further work in this problem will be presented later.

#### CONCLUSIONS

1 The smoking of tobacco in the form of "standard" cigarettes produces in the great majority of normal individuals certain definite pharmacologic effects.

A A marked drop in surface temperature occurs at the tips of the fingers and toes. This varies in different individuals with the same tobacco and in the same individual at different times. The average drop in our series was 5.3 degrees F, the maximum drop was 15.5 degrees F. Surface temperature taken at the forehead and waist did not show a similar change.

B Slowing and stoppage of the blood flow in the capillaries of the nail fold were frequently observed during these tests.

2 The length of time a subject had been a smoker and the number of cigarettes habitually smoked daily had

<sup>13</sup> The Nicotine Content of Tobacco Bureau of Investigation J A M A 101 385 (July 29) 1933

no determinable effect on the degree of the temperature drop

3 Certain subjects showed marked toxic effects from smoking one cigaret under controlled conditions. In each instance, these were experienced smokers who ordinarily note slight or no symptoms from smoking.

4 Very slight, if any, difference could be noted between the effects of standard, demicotinized and mentholated brands of cigarets.

5 No effects on the peripheral circulation could be noted following the smoking of "ashless filter paper cigarets."

6 No direct relationship between the degree of drop in peripheral surface temperature and the skin tests for tobacco and nicotine could be established. (This is a preliminary report.)

7 The lack of symptoms noticed by experienced smokers, under usual conditions of smoking, is probably, at least in many instances, not due to the development of an immunity to the toxins of tobacco smoke but rather to a conscious or subconscious control of the rate and depth of inhalation, which keeps the toxic effects at a submanifest level.

8 Although not definitely proved, the evidence seems to indicate that nicotine is at least one of the toxic factors and that carbon monoxide and the products of the cigaret papers may be eliminated as offending mediums.

## PSEUDO-ANGINA PECTORIS ORIGINATING IN THE CERVICAL SPINE

I WILLIAM NACHLAS, MD  
BALTIMORE

Angina pectoris is a disease characterized primarily by subjective clinical phenomena. There is pain in the left side of the chest, occasionally with radiation of pain down the left arm. Objective clinical methods for the recognition of this disease are generally lacking, so that the patient's complaints must determine the diagnosis. Obviously, if other diseases exist that may give the same type of pain, careful differentiation must be attempted to avoid condemning those suffering with benign ailments to the rigid regimen of the anginal patient.

The importance of this differentiation is exemplified by a patient seen in 1929 for a pain in the cervical spine. This man had been confined to bed for several weeks because of a supposedly bad heart. The internist had found no objective evidence of cardiac dysfunction, but since the patient complained of severe pains in the precordium at times stabbing in character and often associated with radiation down the left arm, the diagnosis angina pectoris was made. Orthopedic examination, made because of some joint pains, revealed an acute arthritis of the cervical spine. Under the use of head traction and salicylate medication the pain in the neck cleared up promptly, and with it the anginal pains disappeared. The patient has since then led a busy life, with plenty of emotional and physical activity, without any anginal symptoms. It is of interest to note that because he was known to have had pain in the left side of the thorax his application for insurance was rejected.

Another clinical experience of interest is that of a young woman who came in because of pain in the neck.

The history revealed the fact that she had anticipated visiting a surgeon because of pain in the right breast, which she feared might be cancer. In spite of the right-sided thoracic pain she did not present any evidence of a malignant condition or of pleural involvement but showed a clear-cut case of cervical arthritis with particular involvement on the right side. Standard treatment for arthritis promptly relieved not only the condition of the neck but also the discomfort in the right breast.

Fig 1—Appearance of cervical spine in a patient suffering with precordial pains. The arrow points to arthritic spiculations.

A third case is that of a physician who was having pain in the left side of the thorax, front and back, and down the left arm. He consulted an internist, who assured him on the basis of his youth and the absence of signs of heart disease that no cardiac pathologic condition was present, but the pain persisted. The suggestion that the condition might arise in the cervical spine was not favorably received until there developed a Horner's syndrome, that is, a drooping of

Fig 2—Origins of the nerves of the brachial plexus (after Cunningham).

the left eyelid and a contraction of the pupil. These eye signs have been traced to an involvement of the nerves originating in the region of the first thoracic vertebra. Clinical and roentgen examinations disclosed a marked arthritis of the lower cervical spine (fig 1).

The common denominator in these three patients is an involvement of the lower cervical spine associated with thoracic pains. It is possible to find one area

which, if it is involved by a lesion, can produce these symptoms, including the Horner's syndrome. A survey of the anatomy of the cervicodorsal spine and of the adjacent nerve structure reveals the following pertinent facts. Nerve fibers originate in the spinal cord, course through foramina in close proximity to the articular processes of the vertebrae, pass through the ramifications of the brachial plexus, and emerge to form various nerves (fig 2). Of these the medial anterior thoracic nerves originating in the eighth cervical and first thoracic spinal segments and the lateral anterior thoracic nerve originating in the sixth and seventh cervical segments innervate the pectoralis major and pectoralis minor muscles. The thoracalis longus, thoracodorsalis and subscapularis nerves begin in the posterior roots of the fifth, sixth, seventh and eighth cervical segments and supply the teres major and teres minor, the subscapularis and the deeper portions of the latissimus muscle. Rami communicantes may arise from the lower portion of the cervical and upper part of the thoracic cord and pass through the cephalic portion of the sympathetic system to assist in the control of eye musculature. It is noteworthy that the nerves enumerated are motor in character, that is, they do not carry any skin sensory fibers. Possibly this was responsible

referred either to the region beneath the scapula or to the precordium. This clinical test inferentially supplies the physiologic correlation necessary.

The clinical picture of patients presenting this syndrome is fairly constant. There may be a history of a strain particularly when the head is in an unusual position. Thus, a sudden lurch to catch a falling child when the head is partly turned away has been reported as a precipitating factor. In some patients occupational strains seemed to be responsible, as in a linotype operator who was myopic and worked with his head shoved forward. On the other hand, the onset may be very insidious, beginning with generalized rheumatic aches that seem to localize in the neck or "shoulder." The patient finds it difficult to stoop forward and particularly to turn his head. A frequent complaint is the inability to find a comfortable position in bed. There may be a constant ache in the upper part of the chest, but movements seem to produce stabs of pain in the thorax, front or back (fig 3). At times the patient also complains of discomfort in the neck, but usually, as in sciatica of lumbosacral origin, the referred phenomena completely overshadow the pain in the spinal column. Diet and emotional factors apparently have no effect on the symptoms.

On examination, the patient frequently presents a lateral deviation of the cervical spine. Muscle spasm is almost always present, involving the trapezius or splenius capitis so that the taut muscle is seen to stand out prominently when compared to the same muscle on the opposite side. The movements of the lower cervical spine are restricted. It is important to observe the actual motion of the vertebrae since considerable movement of the head is obtainable in the upper part of the neck. On palpation one may observe some tenderness over the spinous processes but the characteristic pain on pressure is obtained over the lateral articular processes on the affected side. Most generally one finds a point of exquisite pain on pressure over a spot at the junction of the shoulder and neck in the posterior frontal plane (fig 3). It is important to check the reaction of the patient to the pressure by applying similar point-pressure to the opposite side. (To determine the anatomic structures that may produce the severe pain felt on pressure over this point, a nail was driven into a cadaver in the line of the force. It was found that the nail perforated the skin and muscle and fascial planes and became embedded in the articulation made by the posterior articular processes of the seventh cervical and first thoracic vertebrae.) Rarely one finds an area of hyperesthesia over the chest wall. Roentgen examination often shows arthritic spiculation.

In the differential diagnosis one must bear in mind true angina pectoris, pleurisy, breast tumor, fractured rib, myositis and gastritis. One must examine the patient for signs of heart disease, friction rub, pleural fluids, abnormal masses, and tenderness on deep pressure over the chest wall. It is also worth remembering that the pains of cervical origin are not likely to be substernal, are not brought on by dietary indiscretions, and are not precipitated by emotional stress.

The treatment should be etiologic and need therefore not be discussed at length in this paper. There are, however, a few facts that may be mentioned here. Supportive devices are very helpful. In mild cases restrictive strapping may give relief. In more severe cases any of the usual orthopedic appliances, particularly modifications of the Thomas collar, will give relief.

Fig. 3—Areas of referred pain and characteristic point of local tenderness.

for the failure of observers to correlate the cervical lesion with the thoracic pain. It is, however, clearly established that motor nerves can possess protopathic sensations so that the pinching of such a nerve will produce a definite pain, diffuse in character but referable to the terminal portion of the nerve. In these facts is found an anatomic integration of the cervicodorsal lesion with the symptoms of thoracic pain and oculo-motor disturbances.

Physiologic integration of these phenomena could be accomplished by exposing the roots of the brachial plexus in a patient who is awake, applying pressure stimuli to these roots, and recording the location of the pain in the chest. An opportunity to do this has not presented itself, but a clinical test which inferentially supplies the same compression of the nerves has been noted. Movements of the cervical spine alter the relationship of adjacent vertebrae sufficiently to enlarge or diminish the size of the foramina. If, as a result of swelling of the articular membranes or projection of osteophytes, the size of the foramina has been so encroached on as to leave but little clearance around the cervical roots, there will be produced a compression of these nerves when the neck is tilted in the proper direction. I have noticed in many of my patients with a severe cervical arthritis that acute hyperextension and lateral bending of the head will produce a stab of pain

Occasionally head traction is necessary. Physical therapy likewise can be used with benefit in many instances. One may expect fairly prompt symptomatic relief when such procedures are employed.

## ANALYSIS OF FOOTBALL INJURIES

THOMAS N. HORAN, M.D.  
BLOOMFIELD HILLS, MICH.

The present study includes a record of major and minor injuries through four consecutive seasons at Cranbrook School, where 80 per cent of the boys play football, the average school attendance is 200 boys. The analysis of the injuries is taken from notes entered each afternoon and evening during the season. These injuries are summarized in the tables and presented pictorially in the accompanying illustration. The use of broad descriptive terms—e.g., chest wall in preference to ribs, intercostal muscles, costal cartilages, and ligaments—simplifies and condenses the report to the seventeen items listed in table 1 in the order of frequency.

The total number of injuries decreases: 243 in 1930, 112 in 1931, 68 in 1932 and 75 in 1933. This interesting reduction developed gradually as the causes for special regional injuries were examined in respect to the anatomic strength or vulnerability of the part, the character and direction of the force inflicting the injury, the distribution of padding (cotton, wool, sponge rubber and leather) within the uniform and the style or form in play.

Comments on the causes and samples of the means of prevention of the most frequent injuries are listed.

**The Ankle**—The universal application of ankle bandages (2 inch Ace bandages) effectively protects the region.

**The Fingers and Hand**—Many of these injuries are due to spreading of the thumb and fingers in the process of tackling and straight-arming. Proper spac-

ing of the fingers and careful instruction by the coaches in the correct use of the hands greatly reduces these injuries.

**The Shoulder**—This injury is the result of a sudden, usually an ungraceful, fall on the shoulder point. One interesting variety is a very special strain in the acromioclavicular articulation, requiring from seven to ten days of treatment. These injuries are reduced in number by well padded, carefully fitted, softly kneaded and oiled leather cups over the turn of the shoulder.

TABLE 2—Types of Injuries

	1930	1931	1932	1933
<b>A Fractures</b>				
Finger	3	5	1	2
Face	2	1	3	4
Spine	1	1	0	0
Ankle	1	1	1	0
Shoulder	1	0	0	0
Wrist	1	1	0	0
Knee	0	1	0	0
<b>Total</b>	<u>9</u>	<u>10</u>	<u>5</u>	<u>6</u>
<b>B Dislocations</b>

<b>C Concussion</b>				
Cerebral	1	5	2	0
<b>D Visceral lesion</b>				
Kidney	0	1	1	0

**The Head, Cerebral Concussion**—In the years 1930, 1931 and 1932 there were eight cases of cerebral concussion, five occurring in 1931. The associated dazed and bewildered state persisted from twelve to forty-eight hours, amnesia, especially for events of the day of the game, was most characteristic. The only neurologic finding was the difference in the size of the pupils. Insistence on the wearing of securely laced, well fitted headgear in practice, scrimmage and games is most important. Chin straps should be in place, and the head should be held up sufficiently to follow the play at all times.

**The Spine and Back, Iliac Crest** (lumbar region)—Padding extending well up toward the lower rib margin and over the iliac crest amply protects these regions, with thin boys the padding should be of increased thickness.

**The Knee**—A greater number of knee injuries is responsible for the increase in the total injuries, from sixty-eight in 1932 to seventy-five in 1933. The present season's style of play, featuring lateral passes, double reverses and sweeping lateral runs, may be the cause. The most bothersome knee injury is a tear in the internal lateral ligament. The use of a 6 foot 2 inch elastic bandage, or other special bandages, affords support to the joint.

**The Face, Feet and Chest Wall**—These regions are unprotected, although nose guards and padding could be used, this would be cumbersome and impracticable.

Of importance equal to a consideration of regional injuries are certain general measures: a relatively long period of training before scrimmages are begun, limbering and warming up with brief exercises before the games, daily weighing of the players throughout the season, removal from scrimmage of boys who are losing weight and of players from games who become tired during the closing periods of play, careful utiliza-

TABLE 1—Regions Injured

ing of the fingers and careful instruction by the coaches in the correct use of the hands greatly reduces these injuries.

**The Muscles**—Muscle injuries are due to a direct blow not easily prevented. Two special muscle groups are considered: 1. The muscles passing obliquely downward from the neck to the shoulder which are injured in tackling and blocking to prevent injuries in

Study in collaboration with Mr. John J. Finnesey, coach. The Athletic Coach, October 1933.

tion of the intervals—time out and normal periods for purposes of recuperation, the development of a graceful and effective football form

It is possible that the exhaustion resulting from a strenuous game may be decreased by the use of salt given by mouth, this observation has frequently been made and finds expression in the human craving for salt. Recently there have been more specific measurements of salt balance. One example is the study with

players in this series is 2 pounds (907 Gm.), the administration of salt in capsules and saline solution ( $3\frac{1}{2}$  Gm. per pound [453 Gm.] loss in weight)<sup>2</sup> should hold the blood chloride at a normal level, and, although this remains a theoretical consideration and has not been tried, it might in part overcome the players' sense of exhaustion.

The most serious injuries in 1930, 1931 and 1932 included a fracture of the second lumbar vertebra, a

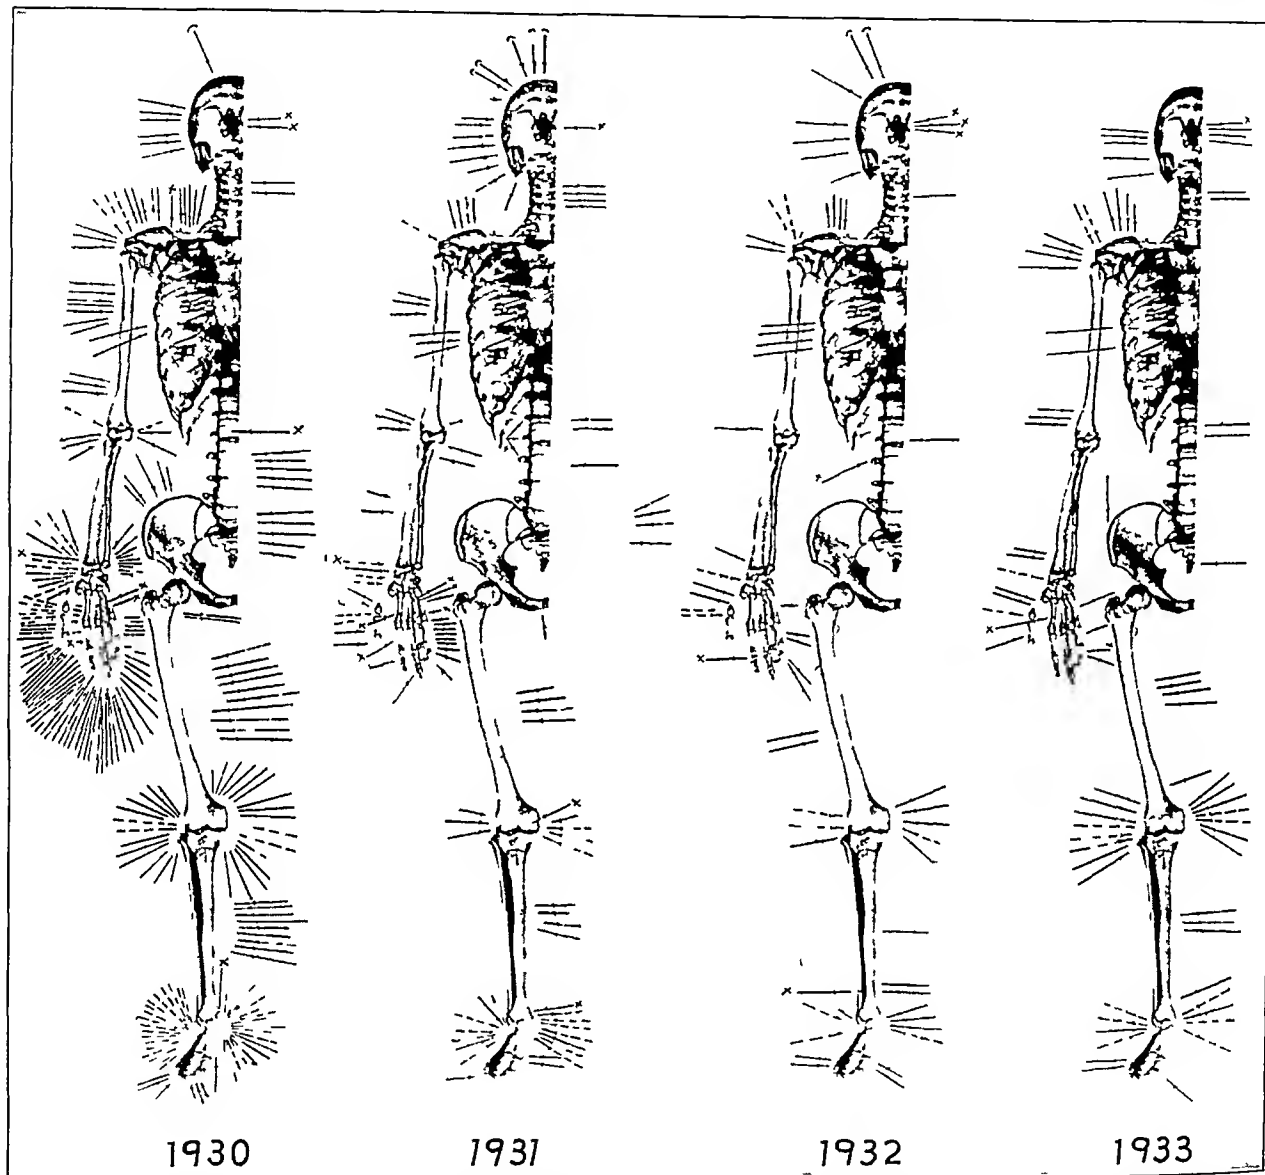

Fig 1—Composite picture of injuries in 1930 1931 1932 and 1933 football seasons. The types of injuries in the accompanying illustrations are indicated as follows: soft parts: solid arrow; ligament: arrow of dashes; fracture: arrow with X; viscous: arrow of dots; concussion: arrow with C.

the "sweat-box" at Dayton<sup>1</sup> where the 20 to 26 Gm of salt lost in a single treatment was replaced by from 4 to 6 liters of 0.6 per cent solution of sodium chloride. This resulted in a restoration of blood chloride to normal and "entirely abolished the sense of fatigue and exhaustion and practically eliminated vomiting, abdominal cramps and muscular twitching."

In a football game from 0 to 7 pounds (0 to 3,175 Gm.) are lost. The average among thirty varsity

kidney blow with gross hematuria, evulsion of bone within the knee joint at the attachment of a cruciate ligament, cerebral concussion, and severe strain of the internal lateral ligament of the knee. There were no injuries to the epiphyseal line.

In 1933 there were no serious injuries. There were two fractures (apart from the nose), one of the third metacarpal and one of the fifth proximal phalanx without displacement of the bone ends, and internal lateral

<sup>1</sup> Simpson, W. M. Ultra High Frequency Pyrotherapy of Neurosyphilis. Preliminary Report. *Ann. Int. Med.* 7: 64 (July) 1933.

<sup>2</sup> This figure is based on a mean between 0.85 per cent (the salt in sweat at rest) and 0.65 per cent (the salt in sweat induced by extremely high temperatures).

ligament (knee) injuries of moderate degree There was an average weight gain in varsity players of  $1\frac{1}{2}$  pounds (680 Gm) during the season

A history of fractures sustained during the lifetime of each boy was obtained The average number of fractures (exclusive of the nose) was 1.47 per boy A history of five fractures, one occurring on each of five separate occasions, was given by two boys In these cases roentgenologic examination of the skull lumbar spine, long bones of the forearm and the pelvis was entirely negative Blood calcium phosphorus and phosphatase were normal From these observations it may be inferred that the bony structures in this group of 200 boys are sufficiently sound to withstand the impacts and stresses occurring in a game of football

## ANTERIOR LENTICONUS

BENJAMIN RONES, MD  
BALTIMORE

The term "anterior lenticonus" is used for conical transparent projections from the anterior surface of the lens into the anterior chamber Several observers have attempted to classify these anterior lens projections further into "lenticonus," of conical shape, and "lentiglobus" of spherical shape Because the slight difference in form bears no relationship to the mechanism of production no attempt will be made in this paper to differentiate the two types, which are the same in all respects other than shape, all will be designated as anterior lenticonus

The anomaly is an extremely rare one, and a careful search of the literature reveals only ten cases in which the diagnosis could not be questioned The transparency and absence of opacity formations in lenticonus allow for its differentiation from projecting anterior capsular opacities The etiology of the two conditions is entirely different Clinically, a conelike or spheroidal structure protruding from the center of the anterior surface of the lens into the anterior chamber is observed by oblique illumination With direct illumination it gives a characteristic appearance of a "globule of oil in water" The center of the lens is highly myopic, while the periphery is emmetropic or even hyperopic Ophthalmoscopic examination of the fundus produces an inverted real image through the lens center, and an upright virtual image through the lens periphery

The ten reported cases of anterior lenticonus in which the diagnosis seems to be unquestionable are as follows

CASE 1—The first reported case is that of Webster<sup>1</sup> (1874) In a man aged 24, both eyes when viewed laterally showed a cone shaped swelling of the lens in the center The swellings were transparent but opacities were present in the posterior part of each lens

CASE 2—Van der Laan<sup>2</sup> described under the name cristallinulus polaris anterior a conical projection of the lens in a man aged 23 The base of the cone comprised about one fourth of the anterior surface of the lens The protuberance was transparent and showed no line of differentiation from the lens substance The condition had existed for eight years and had developed slowly causing a high degree of myopia

CASE 3—Venneman's<sup>3</sup> patient was a woman, aged 20, whose vision in both eyes was very markedly reduced by the central myopia resulting from the lenticonus During childhood the vision had been good but it began to fail at about puberty, six years previously No opacities were present in the lenses

CASE 4—Jaworski<sup>4</sup> reported the case of a man, aged 32, with chronic nephritis, who had noticed decreased vision for several years On the anterior lens surface of each eye there was an entirely transparent, regular, conical projection Retinoscopy showed a central myopia of about 30 diopters and a peripheral hyperopia of 3 diopters Eight months later the lenticonus had disappeared from both eyes

CASE 5—De Schweinitz and Wiener<sup>5</sup> briefly mention a man, aged 20, who came under their observation in a military camp His vision had been defective since childhood and at examination was shown to be markedly reduced "The lenses were small and slightly hazy, and each showed a pronounced anterior cone the tips of which almost touched the posterior corneal surfaces This case was observed only once and the data are incomplete

CASE 6—Frey<sup>6</sup> reported an instance of a man with markedly diminished vision the onset of which he could not recall Oblique illumination showed a small regular cone on the center of the anterior surface of the lens in both eyes The cones were completely transparent with a smooth continuous surface and projected for a distance of about one fifth of the depth of the anterior chamber The diameter of the cones at their base was about one fourth of the lens surface There was a marked central myopia, with a peripheral hyperopia The lenses showed no opacities

CASE 7—Riedl<sup>7</sup> contributed the case of a man, aged 36, who was examined by Eilschmig during the war By direct illumination the condition simulated a keratoconus, its true nature was revealed by oblique illumination The picture was identical in the two eyes with the exception that the right lens showed a radial opacity in the upper periphery while the left lens was entirely clear The vision was markedly reduced There was about 7 diopters of myopia centrally and the periphery was emmetropic

CASE 8—Weiss<sup>8</sup> reported an instance of a man, aged 29 whose vision had been poor since childhood By direct illumination both eyes showed a sharply defined disk in the center of the pupils, giving the "oil drop" appearance The lenses were clear and the fundi were normal Skiascopy showed the central refraction to be -120 diopters and that of the periphery to be +15 diopters

CASE 9—Kienecker's<sup>9</sup> was the first reported case to be observed with the slit lamp The patient a man, aged 42, had had nephritis for eight years, during which time he complained of decreased vision Slit lamp examination showed in both eyes a conical arching of the lens substance at the anterior poles extending for a distance of about 2 mm into the anterior chambers The base of each cone measured from between 3 to 4 mm in diameter The capsular epithelium the contents of the conus and all the remaining lens substances, together with the posterior capsule, were clear It could be seen that the conus contained normal lens substance and that the outer planes paralleled the arch of the anterior capsule By direct illumination the characteristic appearance of an "oil drop suspended in water" was given Skiascopy showed a central myopia of 20 diopters with emmetropia in the periphery The vision was very defective in both eyes

CASE 10—Feigenbaum's<sup>10</sup> case was the second to be studied with the slit lamp It is especially noteworthy because of the length of time the patient remained under observation and because of the changes that occurred during that time A boy, aged 10 years complaining of bad vision was first seen in 1926 Direct illumination showed a "globule of oil in water" exactly

in the middle of the pupil of each eye. The refraction was  $-55$  diopters centrally and  $-10$  diopter in the periphery. In 1929 he was observed and the slit lamp examination showed that the anterior surfaces of the lenses were conically distorted in the middle. Only the anterior layers of the lenses were involved, for the infantile nuclei did not participate in the protrusion. With the higher magnification, delicate granular opacities could be seen in the area of protrusion, situated closely

the posterior corneal surfaces, where they appeared hazy. Both eyes showed microcornea, aniridia and hyperopia.

The second case was that of a boy, aged 17 years, in whom anterior lenticonus developed in the right eye. Within eight months this had become an anterior capsular cataract. An anterior capsular cataract developed also in the left eye. Both eyes showed a marked juvenile arcus.

The explanations offered for the formation of anterior lenticonus are all based on speculative grounds. The case reported by Mohr is the only one that has been investigated anatomically and it was a very doubtful example of the condition. Seefelder and Wolfrum<sup>15</sup> were the only ones who offered an embryologic explanation based on definite observations. Their case will be discussed later.

It is apparent from the manner of onset of the various cases cited that anterior lenticonus can be either acquired or congenital. From Webster's description of his case, the variety of the condition cannot be determined. In van der Laan's case the condition gradually developed over a period of eight years, beginning at the age of 16. The onset was at puberty in Venneman's patient. The condition had its onset during adult life in the cases reported by Jaworski and of Kienecker, while in the cases of Frey and of Riedl the time of onset could not be determined. The story of defective vision since childhood in the patients of de Schweinitz, of Weiss and of Feigenbaum place these cases in the congenital classification.

Krusius believed that anterior lenticonus was always a congenital anomaly resulting from a delayed and abnormal constriction of the lens vesicle from the surface ectoderm, so that a damage of the anterior epithelium of the lens occurred as a result of the adhesion. Ida Mann<sup>16</sup> also favors this view. This theory is completely untenable in view of the fact that in all the

Fig 1—Anterior lens capsule arched forward and separated entirely from the normal lens fiber system in the 4 months old human embryo described by Seefelder and Wolfrum.

under the completely intact anterior capsule. The patient was examined again in 1932, at which time the left eye showed no sign of the lenticonus but only a simple anterior polar cataract.

These ten cases are clear cut and undoubtedly should be classified as instances of anterior lenticonus. The following five cases, also found in the literature, have been called anterior lenticonus, but to me they do not appear to belong in this category.

**CASE 1**—The case described by Krusius<sup>11</sup> was seen in the clinic following a contusion injury of the right eye which had caused a posterior luxation of the lens and a vitreous hemorrhage. The left eye was not injured and examination with the mirror showed a minute droplike structure in the region of the anterior lens pole. It was entirely transparent and projected as a slightly pointed cone being continuously covered by the capsule. The vision in this eye was normal.

**CASE 2**—Mohr's<sup>12</sup> case bears little resemblance to a true anterior lenticonus. The patient was a child, aged 3 weeks, at whose birth bilateral corneal opacities were noted. The right eye was enlarged and the tension was markedly elevated. Because of progressive enlargement the eye was enucleated. The lens was found to have a peculiar shape, anterior surface being elevated like a cone, while the posterior surface was pushed forward into a dimple. The posterior capsule was of normal thickness. The anterior capsule became progressively thinner from the equator forward and at some places on the cone it was entirely invisible.

**CASE 3**—The case reported by Francis<sup>13</sup> was that of a boy, aged 18 years, whose right eye had turned in since birth and showed a 'white spot'. A semi opaque cone was seen projecting from the lens surface, with the apex touching the posterior corneal surface. The base of the cone seemed to spring from a zonular opacity of the lens and came forward through an opening in the outer lens layers. The vision in the eye was reduced to light perception. The left eye was entirely normal.

**CASES 4 and 5**—The first case reported by Tsukahara<sup>14</sup> was that of a boy, aged 1 year, in whom the anterior lenticonus developed shortly after birth. The points of the cones touched

Fig 2—The lens vesicle connected with the surface epithelium in the normally developing embryo of 7 mm length.

typical cases the epithelium and the capsule over the conus are unchanged and show no evidence of opacity formation. That such adhesions between the lens and the cornea can occur is not doubted, and the case reported by Francis is resultant most likely from such a disturbance, but it is not a true lenticonus.

Jaworski was of the opinion that in his case the lenticonus was related to the renal disease, and he explained it as a hydrops of the epithelial cells. Certainly, if this theory were correct one would expect to find the anomaly much more frequently than has been reported. Kienecker's patient also had nephritis with hypertension, and he attempted to relate the lenticonus to a dis-

Fig. 3—The cavity of the lens vesicle reduced to a crescentic shape by elongation of the cells of the posterior vesicle wall in the normally developing embryo of 12 mm length

turbance of the water metabolism, resulting in a swelling of the visible lens margin into the pupillary space.

Venneman attempted to relate the condition to some metabolic disturbance occurring at puberty. The nature of such a change would be very difficult to comprehend.

Von Hess<sup>17</sup> thought that the lenticonus was due to a decreased resistance of the anterior capsule, either congenital or acquired, the weakened capsule yielding to the pressure of the growing lens fibers, which is probably most marked at the anterior lens pole. Elschning's view is that anterior lenticonus is caused by abnormal insertions, position and tension of the three fiber systems of the zonule of Zinn. During the growth of the lens this leads to an irregular form, probably as a result of too slight resistance of the polar part of the capsule. Collins<sup>18</sup> felt that the complete absence of the fibers of the zonule was responsible for the anterior bulging, for under such circumstances there is no mechanism to flatten the anterior surface of the lens. Feigenbaum also believes that a congenital weakness of the central part of the anterior capsule should be held accountable for the anomaly. He also thinks that the anterior lenticonus can increase during the course of life and may sometimes lead to the bursting of the capsule which would cause a flattening of the conus and the formation of an anterior capsular cataract, with a marked improvement of vision.

All these theories are based on supposition. The only definite anatomic evidence to date is that offered by Seefelder and Wolfrum.<sup>14</sup> In a 4 months old human embryo they found a very striking change in the ante-

rior portion of the lens of each eye, which was otherwise normal for that stage of development. The anterior lens capsule was arched forward and separated entirely from the normal lens fiber system. The capsular epithelium was unchanged and covered the capsule continuously. The space between the capsule and the lens substance was filled with a homogeneous substance. The arch of the capsule made an indentation in the posterior corneal surface, but there was no impairment of the corneal epithelium or of Descemet's membrane, and there was no loss of corneal substance. The authors believed that the anomaly represented a retardation of the normal lens development for the following reasons. The development of the human lens begins in about the fourth week of intra-uterine life and the growing fibers reach the anterior epithelium in about the eighth or ninth week. In their embryo, aged 4 months, a space was still present between the epithelium and the lens fibers which represented a retardation of two months in its development. They offered two theories to explain the causation: that it resulted from a large fluid intake from the tunica vasculosa lentis or that a too large albuminous content had interfered with the exchange of fluids.

Seefelder and Wolfrum offered this evidence as an explanation for the origin of congenital anterior lenticonus. They deplored the fact that there was no anatomic material available from a clinically diagnosed case in order to correlate the developmental anomaly with the fully developed condition. They also realized that it would have been possible in their case to have a later resorption of the abnormal lens contents, and thus an apposition of the capsule to the lens substance.

The case that I am presenting tends to confirm the evidence offered by Seefelder and Wolfrum. Further-

Fig. 4—Anterior lenticonus in an embryo of 18 mm length (author's case)

more, their material was rather fragmented by the sectioning of the eye, and the possibility of an artefact could be brought up as an objection to their views. In my case the material is so well preserved that such an objection could not be considered.

In the process of the normal development of the lens the vesicle is still connected with the surface epithelium in the embryo of 7 mm length, but has become entirely separated in the embryo of 9 mm length. An elonga-

tion of the cells of the posterior wall of the vesicle then begins to appear, so that the cavity gradually becomes obliterated. This process is well seen in figure 3, in which the space is crescentic. The elongation of the fibers proceeds, so that in the embryo of 16 mm length the space is practically entirely obliterated, although a potential space still persists for some time. At this stage the hyaline capsule of the lens begins to form, probably as a secretion by the cells of the vesicle. From the 16 to the 26 mm stages of the embryos the lens keeps the same general arrangement, with the central fibers gradually beginning to fade in their staining characteristics. After the 26 mm stage the process of fiber formation takes place in the equatorial region, where the epithelium of the anterior capsule forms the lens fibers.

The specimen is that of an 18 mm human embryo, sectioned coronally. It shows a lens of normal shape, with a smooth, evenly curved anterior epithelium. A hyaline capsule has as yet not become visible. The primary lens fibers are well developed in the periphery. The most striking feature of the lens is the biconvex defect beneath the normal anterior epithelium. The depth of this space is about one-fifth the diameter of the lens. The posterior wall of this space is formed by a sharply defined margin where the lens fibers terminate. There is no evidence of membrane formation to give the posterior wall of the space this smooth edge. The space itself is filled with a homogeneous serous fluid, taking a very faint stain. The lens fibers have a well preserved appearance, with clear cut nuclei. Other than this lens defect, the eye appears to be normal for this stage of development.

The space noted in the anterior portion of this lens undoubtedly represents an anomaly of development. It is not a mere retardation of the normal development, for then the persistence of a crescentic space would be observed rather than one of a biconvex shape. The explanation of such a developmental anomaly can only be a speculative one. The pressure exerted by the growing fiber system within the lens is apparently not great enough to cause the tissue fluid to filter through the anterior epithelium or to become absorbed. As this fluid becomes compressed it exerts a retarding back-pressure on the advancing margin of the lens fiber system and prevents its full anterior development.

The final outcome of such an anomaly cannot be foretold from the limited data that are at hand. It is possible that the fluid may become absorbed and the lens fibers come in apposition to the anterior epithelium, and the lens then go on to normal development. It is more likely, however, that with the increasing pressure exerted by the proliferating lens fibers there will be a bulging of the anterior epithelium, forming the anterior lenticonus of the clinical variety. Whether the serum would remain under such conditions, or whether there would be an ingrowth of lens fibers into this space, would most likely depend on the pressure balance that is maintained.

#### CONCLUSIONS

1 Anterior lenticonus is probably the result of a congenital or an acquired disturbance of the pressure relationships in the lens system.

2 The congenital form bears no relationship to delayed separation of the lens vesicle from the surface ectoderm.

3 The anomaly here presented appears to be the forerunner of the congenital type of anterior lenticonus,

though the possibility of the disappearance of the fluid and an ingrowth of normal lens fibers must be borne in mind.

4 Since this anomaly is present prior to the development of the hyaline capsule and the zonular fibers, it is apparent that the underlying cause of congenital lenticonus is not a deficiency in these structures.

#### ABSTRACT OF DISCUSSION

DR CLAYDE A. CLAPP, Baltimore. The great difficulty in discussing the question of anterior lenticonus is that few ophthalmologists have seen the condition, either clinically or embryologically. It is of interest that the first case to be described (Webster's) was from Agnew's clinic in New York, although published in German. Many of the cases reported as shown by Dr. Rones, developed in young adult or middle life and in some the condition disappeared later. It is my opinion that these are not true lenticonus cases and under more accurate study by means of the slit lamp will be found to be the result of fluid under the capsule, or possibly a cystlike structure that undergoes absorption. Certainly if the condition is in any way analogous to posterior lenticonus there is a structural change in the lens itself, which in my experience is always congenital in character. As to the etiology it would seem that the congenital type is entirely different from the acquired. In the congenital variety I could imagine that a delayed separation of the lens vesicle from the surface epiblast might cause some alteration in shape of the lens without leaving an opacity although this would be very unusual. Von Hess and Feigenbaum's idea that a weakened capsule is the cause of bulging in this sector is not borne out by the slit lamp illustrations of either Kieneker's or Feigenbaum's cases. Collins and Mayou's theory as expressed in their textbook "Pathology and Bacteriology of the Eye" is not quite the same as given by the author. Instead of a complete absence of the zonular fibers, they state, "its occurrence may be attributed to the failure in development of the orbiculo-anterior-capsular fibers of the suspensory ligament, which stretch from the capsule to the hindmost part of the ciliary body." The lack of traction of these fibers allows the lens to bulge forward at its center. This explanation, however, seems to be highly theoretical. The theoretical explanation from the embryologic studies of Seefelder and Wolfrum supplemented by those of the author seems to be more logical than most of those which have been advanced and I hope that some actual clinical cases can be studied in order to clear the question. The etiology of the acquired cases of anterior lenticonus can be elucidated by a careful slit lamp study with especial reference to changes in the lens substance itself. I therefore urge that if any ophthalmologists should see such a case they have a study made.

DR BENJAMIN RONES, Baltimore. In view of the fact that this is only an embryonic specimen, these observations cannot be related to those seen in the adult lenticonus.

**The Evolution of Specialists**—The old plan of the natural evolution of specialists from general practitioners is much more desirable than the newer one of producing them, as it were artificially and often without adequate general training. In the practice of internal medicine the chief danger of specialism lies in the detachment of the specialist, particularly the laboratory specialist, from the family doctor—a detachment which is unavoidable because of the complicated and time consuming character of many of the newer tests. The radiologist, for example, hardly ever knows the complete history or makes a general physical examination of the patient whose structures he is illuminating. Laboratory technicians often interpret their findings among the secreta and excreta quite positively without knowing anything about the patient who furnishes the specimens. The result is not infrequently misleading and occasionally disastrous unless the general practitioner is capable as he should be of interpreting the laboratory findings in the light of his general knowledge of the patient.—Blumer, George. Some Discursive Remarks on Bedside Diagnosis. *J. Biol. & Med.* 6: 571 (Jul.) 1934.

# SENSITIVITY TO FUNGI IN INFANTILE "ECZEMA"

LEWIS WEBB HILL, MD  
BOSTON

There are many factors in the etiology of what is ordinarily somewhat loosely called "infantile eczema," and there can be no clear understanding of the disease until bit by bit the significance of these factors is determined

In the last few years fungi have assumed great importance in dermatology, and it has been shown for adults that many eruptions previously classed as "eczema" are in reality fungous infections. Certain of these present a characteristic morphology, such as the lesions on the palms and soles and between the toes in what is usually called "epidermophytosis," but it is true that the most varied morphology may be seen, and for this reason it may be impossible to diagnose many fungous infections without obtaining scrapings or cultures from the lesions

The fungi that have most often been found in eczema-like eruptions are of two groups: the "yeast-like" forms (cryptococci and monilias) and the trichophytons. The cryptococci multiply by budding and have no mycelia, the trichophyton group, or molds,

fungi have a low pathogenicity, some of them probably have no pathogenicity at all, and many of them occur frequently on normal skin, so that their possible pathogenicity is hard to determine. Bloch<sup>1</sup> recovered yeastlike forms from the skin in twenty-two out of twenty-four normal individuals. Benham and Hopkins<sup>2</sup> recovered yeastlike fungi and certain monilias from the nails and skins of 72 per cent of 100 normal

Fig. 1—Monilia test positive. Note sharply defined area on inner side of left thigh. This patient had in addition an ordinary atopic eczema and was sensitive to several foods

have no bud forms but show characteristic mycelia. The monilias stand midway between the two: they are yeastlike in that they grow by budding but also show mycelia on certain culture mediums. Most of these

Fig. 2—Monilia test positive. Apparently a primary fungous infection which responded rapidly to antiparasitic treatment

persons. *Monilia albicans* or members of the trichophyton group are not ordinarily recovered from normal skin, however. *Monilia albicans* is the organism of thrush and is distinguished from other probable non-pathogenic monilias by slight morphologic differences on various culture mediums. The intensive study of mycology is comparatively new and has been made particularly complicated by differences in nomenclature used by various workers and by difficulties in classification, so that the task of making cultures and identifying accurately the various species is for the trained mycologist or for dermatologists who have made a special study of it, and certainly nothing for any practicing pediatrician to take up.

In view of the recent work, which shows that yeastlike fungi can be recovered from so many normal skins, it becomes of doubtful diagnostic value to recover them from pathologic skins, unless the organism can be definitely identified as *Monilia albicans*.

Some mycologists would probably not even agree with this, and there is so much conflicting opinion among them that it is indeed hard for a simple pediatrician to evaluate the available data. There does not seem to be so much difference of opinion about the

From the Department of Pediatrics, Harvard Medical School and the Eczema Clinic, Children's Hospital.

I am indebted to the many dermatologists who have helped me so much and who have been so unfailingly courteous and cooperative in the many discussions I have had with them in the last few years, particularly Dr. Marion Sulzberger of New York, who suggested this investigation.

<sup>1</sup> Bloch, Bruno. *Brit. J. Dermat. & Syph.* 42: 569 (Dec.) 1930.  
<sup>2</sup> Benham, Rhoda W. and Hopkins, Anne McH. Yeastlike Fungi Found on the Skin and in the Intestines of Normal Subjects. *Arch. Dermat. & Syph.* 28: 532 (Oct.) 1933.

trichophytons, and most would agree that, if members of this group are recovered from skin lesions by either direct scraping or culture, they are causative in producing the lesion. It may not always be possible, however, to obtain these organisms, either monilias or trichophytons, from lesions that are clinically fungous infections.

But little work has been done with infantile eczema. Cleveland White<sup>3</sup> was able to grow yeastlike forms

an intracutaneous tuberculin reaction. The mechanism of sensitivity also is probably very similar to that in tuberculin sensitivity, and immediate wheal reactions are rare. The diagnostic value of this test in adults is not great, because so many apparently normal individuals, who have no clinical symptoms of mycotic infection, give strongly positive tests, exactly analogous to the situations in tuberculin sensitivity. It seemed possible, however, that it might be of more diagnostic value in babies and young children than it is in adults, just as is the tuberculin reaction.

#### TECHNIC OF TEST

One-tenth cubic centimeter of "oidiomycin" (Lederle),<sup>4</sup> a 1 to 100 dilution of an extract of a pathogenic strain of *Monilia albicans*, or the same amount of 1 to 100 "trichophytin" (Metz), an extract of various strains of trichophytons, is injected intracutaneously into the forearm and observed at the end of forty-eight hours. A positive test is exactly like a positive tuberculin test, evidenced by an area of inflammatory redness and infiltration, which persists several days and then gradually fades, often leaving a little brownish pigmentation and scaling.

Sixty eczematous infants and young children, with out regard to the type of eczema, were tested with the trichophyton extract, with only two doubtfully positive reactions.

One hundred were tested with the monilia extract, with fifteen positive reactions, most of them very pronounced. There were three positive reactions in infants under 1 year, three in children between 1 and 2 years, and nine in children over 2 years.

It is obvious that no conclusions can be drawn as to the value of this test unless it is determined how frequently it occurs in children who have no eczema. It seemed evident that trichophytin sensitization is of very little importance in infants and children, so no series of normals was studied with this test.

Fig. 3.—*Monilia* test positive. Skin lesion resembled seborrheic dermatitis. Also a great deal of greasy scaling on the scalp. The condition was cured with sulphur and salicylic acid ointment.

from 77 per cent of thirty-two cases of infantile eczema of the usual facial type. This was done, however, before the significance of *Monilia albicans* was clearly established, and he reports them as "cryptococci," without any attempt at differentiation into species, and says quite conservatively that he is not certain whether they are saprophytic or parasitic. A few isolated cases of definitely proved skin infection in infants with *Monilia albicans* or trichophyton have been reported in the literature, but it is not at all certain how common these infections are. It is often not possible to diagnose them by clinical observation and it would be of great advantage if there were some relatively simple test that could be used clinically by pediatricians, for the processes involved in differentiating these fungous forms by culture are too complicated except for expert mycologists, and there are not many of these in the country.

For some years dermatologists have known that in trichophyton and monilia dermatoses there is not only infection but sensitization as well, so that the skin, when injected with extracts of monilia or trichophyton, will give an inflammatory reaction. This reaction is of the delayed type, i. e., appears in from twenty-four to forty-eight hours, and is in appearance exactly like

Fig. 4.—*Monilia* test positive. This child was 2½ years old. The skin lesions resemble more the adult type of fungous infection.

The monilia test was done on thirty infants under 2 years of age and on thirty children between 2 and 12 years, none of whom showed evidence of any skin disease. One strongly positive and one weakly positive reaction were found in the first group and one strongly positive and two doubtfully positive in the second group, a percentage of 8 for the whole group, as con-

<sup>3</sup> White, Cleveland. Superficial Yeast Infections of the Glabrous Skin. Arch. Dermat. & Syph. 18: 429 (Sept.) 1928.

<sup>4</sup> I am indebted to Dr. Arthur F. Coca of the Lederle Laboratories for supplying me with this extract.

trasted with a percentage of 15 for the eczematous group

#### COMMENT

Clinically, trichophyton infection, with the typical lesions between the toes and on the palms and soles, is exceedingly rare in infants and young children, and it seems from the results of the test also (two doubtfully positive reactions in sixty cases) that it can be

Fig 5—Monilia test positive also sensitive to several foods. This was probably a primary food atopy plus a superimposed fungous infection

excluded as a factor of any importance in the eczema of infants and children

The situation is different with monilia, and although positive tests were obtained in 8 per cent of normal children, the fact that twice as many eczematous children gave positive tests make it apparent that monilia infection may be of considerable importance. This is even more apparent when the characteristics of the skin eruptions found in those who gave positive tests are taken into account. No infant who had the usual allergic, vesicular oozing type of facial eczema gave a positive test. One infant who had a seborrheic type of eruption over the scalp and face gave a positive reaction. For the most part, those who gave positive reactions had three types of eruption

1 Dry, rather smooth rather sharply defined areas in large patches on the inner side of the thighs, very similar to eczema marginatum or "red flap" in adults only usually more extensive and more superficial (fig 1)

2 Patchy areas on the body somewhat resembling seborrheic dermatitis (figs 2 and 3)

3 Scalp lesions of the fingers, sometimes with involvement of the nails (fig 4)

Fungous infection may be primary or it may be superimposed on an ordinary atopic eczema, for most of the fungi are of such low pathogenicity that some primary irritation of the skin may be necessary before they can gain a foothold. It was quite evident that in more than half of these cases there was an atopic eczema as a background (evidenced by positive skin tests to proteins, history and so on), but in others it was equally evident that there was no background of any other primary lesions and that the fungous infection, if it was a fungous infection was primary (figs 5 and 6)

Sometimes there may be several factors involved as in one instance in which there was an undoubted atopic eczema from food sensitivity an extensive ammonia dermatitis of the buttocks, and a probable monilia infection on the inner side of the thighs. In this case it was possible to cure the ammonia dermatitis very quickly by appropriate treatment. The lesions on the inner side of the thighs were obviously of different origin and persisted long after the ammonia dermatitis was cured

It is plain that it is not proved that any of these lesions are due to active monilia infection, because no

Fig 6—Same patient as in figure 5 after five weeks treatment which was combined antiparasitic and dietary

cultures were made and because the intracutaneous test was positive in a certain number of normal controls. Monilia sensitization however, is proved. This type of sensitization proves invasion of the host, that there has been infection in the past, or that there is active infection at present, and it seems that the intracutaneous test in infants and children is probably more indicative of active infection than the recovering of "yeastlike organisms." The fact that most of the

patients with positive tests had fairly characteristic lesions makes it very probable that they were monilia infections. For practical purposes, for pediatricians, especially, who are not mycologists but who, after all, see many cases of eczema in infants and children, the test is of considerable value in indicating a possible fungous infection, for, if fungous infection exists, the treatment may need to be entirely different from that employed in the ordinary case of eczema. The test is easy to do and easy to read, and if other observers get results similar to mine it should prove a worth while test in suspected cases of monilia infection in infants and children.

#### SUMMARY AND CONCLUSIONS

1 Trichophyton infection is probably of very little importance in the eczema of infants and children.

2 Fifteen per cent of eczematous infants and young children gave positive intracutaneous tests to an extract of *Monilia albicans*. Eight per cent of a series of normal controls gave positive tests.

3 The monilia test is much more valuable as a diagnostic procedure in infants and children than in adults, just as the tuberculin test is, and in younger groups these two tests have much the same significance.

4 It is likely that monilia infection is of importance in infantile "eczema," and the monilia test is worth while doing in all cases that show scaly lesions on the inner side of the thighs, around the anus, on the fingers with involvement of the nails, or patchy flat lesions on the body. It cannot be said that the cases reported here are proved cases of monilia infection. The evidence available indicates very strongly that they may be

## COTTONSEED ALLERGY

SAMUEL J. TAUB, MD

Assistant Professor of Medicine Rush Medical College of the University of Chicago. Professor of Medicine Cook County Graduate School of Medicine. Member of Attending Staff Cook County Hospital CHICAGO

The role of cottonseed as an etiologic factor in asthma, perennial hay fever, eczema and urticaria has not been sufficiently emphasized in the literature to the present time. Most allergists consider cottonseed sensitivity as not particularly common but a very potent factor in producing severe symptoms. These patients are consequently difficult to treat.

Aaron Brown<sup>1</sup> states that 2 per cent of allergic patients react to cottonseed, while Cooke<sup>2</sup> finds 0.6 per cent. These authors, however, do not mention the total number of patients tested. G. T. Brown<sup>3</sup> reports that 2.4 per cent of 530 patients reacted to cottonseed, but he does not state whether these 530 patients were definitely allergic to other substances.

The basis for my report comprises 246 allergic patients, who had complete skin tests with some 300 separate allergens. Thirteen reacted specifically to cottonseed. Of this group, six patients had asthma, two patients had urticaria, two patients had eczema and three patients had perennial hay fever. This series would indicate that 5.3 per cent of allergic patients are sensitive to the protein of cottonseed, a figure relatively higher than was previously reported. In testing

these patients, I employed the scratch test, with dry cottonseed extract. Intradermal testing is extremely dangerous because of the violent constitutional reactions that may follow.

One of the patients in this series was tested intradermally with a 1 to 1 million dilution and within five minutes a violent asthmatic seizure ensued, which finally subsided after the use of 2 cc of epinephrine hydrochloride 1:1,000 given in divided doses. The patient reacted locally to a 1 to 10 million dilution, the wheal being the size of a dime (18 mm), and desensitization was started with a 1 to 20 million dilution.

There is considerable danger in attempting desensitization, since even the smallest doses and the slightest increase in dosage may produce systemic reactions. It is therefore far safer to avoid contact to cottonseed than for one inexperienced in allergy to attempt desensitization.

Patients sensitive to cottonseed usually manifest an eosinophilia somewhat higher than the average allergic individual.

The cotton plant and the kapok tree are botanically related. Their seeds contain atopen substances which are in part identical, for Coca and Grove have shown that the atopens of the kapok seed are found in cotton seed. The reverse, however, does not hold true. Hence all patients sensitive to kapok seed are also sensitive to cottonseed, but only some of those sensitive to the latter show positive reactions to kapok. Cottonseed sensitive patients also manifest a tendency toward hypersensitiveness to other seeds and to members of the pea, bean and nut families.

The active principle in cottonseed is probably a protein. Clinically, these patients can tolerate contact with cotton fiber of the highest grade without difficulty, but they are troubled by cheaper products which contain some of the seed.

The oil of cottonseed contains active atopen and may induce symptoms as an inhalant, ingestant and contactant. It is almost impossible to state all uses to which cottonseed and its products may be put or to determine all forms in which the active atopen principle may cause trouble to the hypersensitive patient. Cotton (*Gossypium herbaceum*) is raised primarily for its fiber, which is used in the textile industries. Of far more importance to the allergist are the cottonseeds which are separated from the fibers by the cotton gin. To express the oil from the seeds, the hulls or outer coatings must be removed first. These hulls, when mixed with cottonseed meal, are used as cattle food, cottonseed hulls dyed green are used on the greens and fairways of some miniature golf courses.

The finest grade of cottonseed oil is obtained from seeds by pressing them before heating or cooking, and this product is known as cold drawn oil. Other grades are obtained by pressing seeds that have been heated.

The various sources of cottonseed as an ingestant, inhalant and contactant are here enumerated:

Ingestant 1 Salad oils 2 Lard substitutes 3 Butter substitutes 4 Packing sardines 5 Setting olives 6 Cooking purposes 7 Frying potato chips 8 Frying fish 9 Bakery goods 10 Often used by confectioners as a coating to hold chocolate firm 11 Wesson oil, a pure grade cotton seed oil 12 Crisco, hardened cottonseed oil 13 Cottolene, beef suet and cottonseed oil

Contactant 1 Used in cosmetics 2 Used by druggists as a substitute for olive oil in the compounding of emulsions 3 As a base for liniments 4 Used in salves 5 Camphorated oil

<sup>1</sup> Brown, Aaron. New York M J 118 333 (Sept 19) 1923  
<sup>2</sup> Cooke, R. A. J Immunol 7 147 (March) 1922  
<sup>3</sup> Brown, G. T. Cottonseed and Kapok Sensitization J A M A 83 370 (Aug 3) 1929

Inhalant 1 Mattresses 2 Pillows 3 Cotton blankets  
4 Stuffing in furniture 5 Greens and furrows of miniature  
golf courses 6 Cattle food

It is therefore evident that there are numerous sources of contact to cottonseed, and in order to avoid all possible exposure as a contactant, inhalant and ingestant, one should be familiar with the various substances mentioned

A common source as an inhalant is the mattress. In this event it is simple to cover the mattress with rubberized sheeting or any other impervious material. In some cases a kapok or hair mattress may have to be substituted.

Although the role of cottonseed is emphasized as a potent cause of allergic symptoms its complete elimination from the patient's environment can usually be accomplished with marked beneficial results. Owing to the grave dangers in desensitization to cottonseed only those adequately experienced in the field of allergy should undertake this delicate procedure.

## Clinical Notes, Suggestions and New Instruments

### MASTITIS GARGANTUAN AN UNUSUAL CASE OF PUBERTY HYPERTROPHY OF THE BREASTS

B. A. GOODMAN, M.D., NEW YORK

Pathologic breast enlargement of varying degrees has been observed in our clinic, but rarely is the opportunity afforded to present a case of such unusual interest as the one herewith reported.

#### REPORT OF CASE

**History**—E. S., a white girl aged 14, complained of progressive, painless enlargement of both breasts over a period of twenty months, beginning eight months prior to the onset of menstruation, which occurred at the age of 13.

There was no history of similar breast enlargement, or of any breast disease, in other members of the family. The patient is the oldest of six children (five girls and one boy). None of the others have as yet reached the age of adolescence.

No other abnormal physical development was apparent in the patient, and there was no evidence of endocrine dyscrasia or altered secondary sex characteristics. Menstruation since its onset was regular, and of the 5-28 type. The patient showed mental alertness and average normal cerebration for her age. Her seventh grade junior high school work was interrupted on account of the embarrassing breast enlargement.

The breasts enlarged uninterruptedly until they attained the sizes indicated in figure 1.

With the patient standing, the right breast measured 27 inches (67.5 cm) in length, whereas the left one was only 21 inches (52.5 cm). The asymmetry developed and became accentuated during the past year. Each breast, however, maintained its relative proportions, i.e. the size of the nipple and the areola in relation to the size of the entire breast.

No history of trauma was obtained and no pain in either breast was complained of. At no time was there any discharge from either nipple.

**Operation**—A bilateral simple mastectomy was effected with the greatest possible facility and without particular regard for temporary cosmetic result it being deemed advisable to devote time to plastic reconstruction of the mammary area at a time more favorable to the patient. Prolonged anesthesia might undoubtedly have only added to the associated hazards of shock and blood loss.

After the operation an interesting observation was recorded. The absence of the accustomed pull by the weight of the

breasts almost caused the patient to fall backward to the floor when she attempted to walk on getting out of bed the first time.

Pathologically, the diagnosis by Dr. L. H. Mecker (assistant professor of pathology and bacteriology at the New York Post-Graduate Hospital, Columbia University) was "bilateral

Fig. 1—Appearance of patient on admission

hypertrophy of the breasts. Diffuse chronic productive mastitis with marked glandular hyperplasia and associated fibroadenoma."

The right or larger breast (fig. 2) weighed 25 pounds 14 ounces (11.8 Kg) and measured 40 by 35 by 30 cm, whereas

Fig. 2—Cross section of larger breast in a perpendicular plane through the nipple to the pectoral fascia. A, nipple; B, fatty tissue; C, fibroadenoma lying on pectoral fascia. All the darker areas are mammary glands and the very pale areas are myxomatous fibrous tissue.

the left or smaller breast weighed 15 pounds 12 ounces (7.1 Kg) and measured 34 by 30 by 17 cm. The nipples were centrally placed and normal in appearance. With the exception of a small ulcerated area 25 mm in diameter on the

larger breast, the skin of both breasts was normal in appearance. Coarse lobulations of gland tissue were palpable throughout both breasts.

On perpendicular section through the nipples to the pectoral fascia the two breasts presented the same structure. There was diffuse proliferation of edematous fibrous tissue throughout. Aggregations of glandular elements ranging in size from a few millimeters to 5 or 6 cm in diameter were embedded as scattered bright pink somewhat spongy areas throughout the fibrous tissue. There were a few scattered masses of bright yellow fat with lobulations, and there were also many dilated lymph spaces and a few dilated blood vessels.

Tissue for microscopic examination was selected at points 5, 10, 15 and 20 cm distant from the nipple in a straight line to the fascia, and 20 cm laterally, from the larger breast, and at random areas in the smaller breast.

Microscopic sections showed diffuse fibrous tissue proliferation, most of which was very edematous and decidedly myxomatous in type. About the glandular masses, the fibrous tissue was more dense and even hyaline in character. The gland ducts, acini and lobules showed marked hyperplasia with ducts and acini separated by large amounts of fibrous tissue.

Several layers of cuboidal epithelium, presenting no abnormalities outside of hyperplasia, lined the ducts and acini, the lumens of which not infrequently were filled with exfoliated epithelium. The stroma in many of the glandular masses showed inflammatory reaction varying from simple mild infiltration by lymphocytes to a diffuse proliferation of young fibroblasts densely infiltrated by lymphocytes and mononuclear cells.

A single, well encapsulated mass (fig 2C) of glandular tissue 70 by 55 by 55 mm in diameter formed of markedly hyperplastic glands with ducts and acini separated by a small amount of fibrous tissue constituted an associated fibroadenoma.

#### COMMENT

Several designations of nomenclature have been applied to this type of breast condition, yet most of them merely imply variations in degree of similar pathologic changes. Heyd's<sup>1</sup> designation of mastitis gargantuan is unique in its conception. Macromastia, colossal mammary hypertrophy and hyperplasia are other terms applied. Puberty hypertrophy or hypertrophy

Fig 3—Area at lateral margin of the breast near B figure 2 (Medium high power)

in adolescence are more applicable than virginal hyperplasia, a term sometimes employed inaccurately to signify hypertrophy of the nongravid state.

#### SUMMARY

1 Puberty hypertrophy is a comparatively infrequent disease usually seen at the beginning of puberty, but it may occur even earlier.

2 Both breasts are practically always involved, sometimes with marked difference in size. The period of development is

approximately twenty months in those who are under 21 years of age.

3 The breasts usually become pear shaped, markedly pendulous sacs suspended by comparatively slender pedicles (as a result of the traction). A chronic edema from circulatory disturbance invariably ensues.

4 There is uniform and proportional enlargement of all elements and components, with preservation of normal form and structure.

5 Pathologically, lobular formation of the gland is recognized by palpation of nodules or so-called nodular gland complexes. As a rule, too little account is taken of the different stages of maturity of the lobular structure.

Fig 4—Fibro-adenoma near pectoral fascia (C fig 2). Marked glandular hyperplasia (very low power)

6 Cut surface shows the gross pathologic condition of homogeneous whitish masses radiating out into sparse fatty tissue and nodules of glandular parenchyma.

7 Microscopically, both the glandular and the interglandular stroma show hypertrophy and hyperplasia.

8 Differential diagnosis must be made from pseudohypertrophy due to neoplasm and elephantiasis.

9 The true etiology of puberty hypertrophy is obscure.

#### DICK TEST IN CHILDREN

CLARENCE A. EARLE, MD, DES PLAINES, ILL.

My records show that of a large number of children who have been Dick tested and retested from two to ten or twelve times during the past ten and one-half years a relatively large number have shown such irregularities in reaction that my faith in the specificity of this test has been shaken. The claims of specificity are further challenged by the frequent reports of Dick negative children getting scarlet fever. Convinced as I had been of the reliability of the Schick test I was slow to believe that such discrepancies could occur with the Dick test. I have never seen a case of true diphtheria in a Schick negative child, but I have records of eight Dick negative children who later contracted scarlet fever. In justice to the accuracy of this test I must state that five of the eight had also given one or more positive Dick tests.

It is embarrassing to assure a mother that there is no danger of her child getting scarlet fever because he gave a negative Dick test and then to be called in later and find that the child has scarlet fever. It is true that much of my work has been done hurriedly. The interpretation of the test is sometimes difficult. The size and depth of color or even the presence of a macule at all may be subject to dispute. The Dicks say that the faintest discoloration of the skin, if large enough, is a positive test. In order to detect such faint reactions, the light must be correct and a proper angle of the observer's eye must be maintained. The skin must be completely relaxed. Often it can be made plainer by stroking the skin with the finger

<sup>1</sup> Heyd, C. G. Personal communication to the author. From Clinical Lectures, New York Post Graduate Hospital, Columbia University.

I have found that the time of reading the test sometimes, not often, makes a difference. After making allowance for differences that may be due to interpretation, I am forced to the conclusion that something must be wrong with the technic which we were taught to employ. The immunity status of a child does not change over night. A child who is Dick negative today does not get scarlet fever next week.

I here offer a preliminary report of some experimental work that I have recently done as a probable explanation of these irregularities occurring in the Dick test.

The technic of the intracutaneous test devised by Schick and popularized by Park and Zingher has dominated the technic of this procedure whenever and wherever an intradermic test has suggested itself. In my experience the local reaction of the Schick test is slightly, if at all, influenced by the depth into the skin in which the toxin is injected. I demonstrated this to my own satisfaction years ago. The results are different with the Dick test. About two months ago I began giving two simultaneous tests to each child that I tested. One test was given according to the usual instruction, namely, into the superficial layer of the skin, so that the conventional wheal with its hair follicles appeared. The other test was given deeply into the corium, and in a few instances it was almost subcutaneous.

I have to date tested 135 children in this manner with the result that the shallow test gave 14 per cent positive and the deep test 52 per cent positive tests. In only four instances was the macule produced by the shallow test equal to or greater in size than in the deep test. Every child who gave a positive test in the shallow tested group gave a positive test in the deep tested group. Not one child that gave a negative test in the deep tested group gave a positive test in the other group.

I believe that there is an anatomic physiologic basis for this selective susceptibility of the deeper layers of the skin to the scarlatinal toxin. The layers of the skin develop from different embryonic layers: the epidermis from the ectoderm and the corium from the mesoderm. Louis Dienes has shown that the epidermis is relatively more susceptible to certain toxins than is the corium. Certainly there can be no inherent reason why the deeper skin layers could not be more susceptible to the scarlatinal toxin than the epidermis.

I realize that a group of 135 is rather small on which to base such revolutionary conclusions; however, the uniformity of the results is certainly significant at least.

Since the injection of the toxin into the deep layers of the skin results in three or four times as many positive reactions as it does when injected into the superficial layers, it is reasonable to assume that the deeper injection is the correct technic. By following this technic more children will be found to be susceptible, but the immunity status of the child will be more accurately determined.

#### ASPIRATION OF BARIUM FACILITATING DEATH IN A DEBILITATED PATIENT

S. J. SULLIVAN, M.D., CHICAGO

This case is reported because of the relative rarity of fatalities in connection with gastro-intestinal roentgenograms of persons who do not have fistulas between the alimentary and the respiratory tract.

#### REPORT OF CASE

Mrs. C, aged 70, admitted to the hospital March 1, 1934, following forty-eight hours of severe vomiting, had had a cerebral hemorrhage in 1929. She was icteric in color, with symptoms of gallbladder disease, a chronic myocarditis and an advanced arteriosclerosis. Dizzy spells and loss of weight had been increasing complaints for the past five years. The blood chemistry showed an increased nonprotein nitrogen and the urine showed a trace of albumin and casts. The blood pressure was 118 systolic, 78 diastolic and there was a leukocytosis of 13,000 with 86 per cent polymorphnuclears.

The vomiting had produced an extreme dehydration and debility and was caused by any food or liquid. It was spasmodic. Subcutaneous fluids and intravenous dextrose improved

the general condition and strength of the patient so that, March 4, a roentgenogram was taken of the gallbladder, which showed at least one large stone. On this date liquids were tolerated by mouth in small quantities. The morning of March 6 the patient was still improving and feeling better than at any time to date. She was sent to the x-ray department for a gastro-intestinal series.

The patient was placed on a motor driven x-ray table and was given one glass of barium, which she took with only a little difficulty. During the second glass, taken in a semi-horizontal position, the patient suddenly vomited, coughed and then aspirated a fair quantity of the barium, which can be seen in the accompanying illustration. The roentgenologist reported that the fluoroscopic examination of the chest disclosed a marked increase in the transverse diameter of the heart. The contour was relatively normal. The esophagus was deviated in the cardiac region, evidently as a result of the cardiac hypertrophy. There was cardiac spasm present, which was rather persistent, with moderate esophageal dilatation above. The stomach was of the normal hypotonic type; the motility was not ascertained. The bulbous duodenum was normal as to filling contour and mobility.

Roentgenogram showing barium aspirated while vomiting and coughing.

The patient was unable to cooperate further, and when she swallowed the barium she aspirated some of the opaque meal into the lungs. The examination was immediately discontinued and the patient returned to her room.

The primary gallbladder films taken forty-eight hours prior to this examination disclosed the presence of at least one large gallstone.

At 10 a. m. the patient was returned to her room in marked shock, ashen gray and cyanotic, with an imperceptible radial pulse and a rapid heart action. At 12 50 p. m. the radial pulse was still imperceptible, the pupils were pinpoint in size and did not react to light or in accommodation. The reflexes on the right side were exaggerated but were absent on the left. There was a drooping of the right corner of the mouth, and the tongue deviated to the left. The blood pressure had fallen to 90 systolic, 60 diastolic, and the patient died at 4 30. Autopsy was refused by the family.

#### COMMENT

Reports of fatal cases have in most instances been of infants or adults with tracheo-esophageal fistulas.

According to the literature, the barium particles have three means of exit from the lungs: first by coughing, second by the ciliary action on the bronchi, and third by the macrocytes carrying the barium particles away to the lymph channels.

A similar case was reported by Lynch and Stewart<sup>1</sup> in 1915, in a man aged 65, with an esophageal obstruction. Some bismuth passed into the trachea and gravitated to the base of the lungs, but, except for some coughing up of bismuth particles, no bad results were ascertained in his case.

Jackson<sup>2</sup> in 1918 reported a case. He had a healthy man insufflate dry bismuth subcarbonate for roentgenography of the bronchial tree with no untoward results.

Fishel<sup>3</sup> reported a case in a woman, aged 40, showing little or no effects of barium from aspiration.

<sup>1</sup> Lynch H. L. and Stewart W. H. Roentgenographic Slides of the Bronchiectasis and Lung Abscesses After Direct Injection of Bismuth Mixture Through the Bronchoscope. *Ann. Surg.* 73: 362 (March) 1921.  
<sup>2</sup> Jackson, Chevalier. Foreign Bodies in Air and Food Passages. *Surg., Gynec. & Obst.* 26: 201 (March) 1919.  
<sup>3</sup> Fishel C. R. Inhalation of Barium in Solution. *J. A. M. A.* 80: 102 (Jan. 13) 1923.

Many other case reports are on record which confirm these observations. Bullowa and Gottlieb's<sup>4</sup> experiments on barium and thorium nitrate in dogs showed rapid removal of the foreign substances from the lungs.

## SUMMARY

In this case, a markedly debilitated, aged woman with a weakened heart, a marked arteriosclerosis, a cholelithiasis and a dehydration was given a barium meal in a semireclining position. Aspiration probably caused by a cardiospasm produced immediate shock, which either directly or indirectly led to a cerebrovascular accident, which caused her death.

2630 East Seventy-Fifth Street

## A METHOD OF DRYING WOUNDS

JOHN T. BURTON, M.D., OKLAHOMA CITY

Instructor in Surgery, University of Oklahoma School of Medicine

In treating extensive burns with tannic acid spray, one is concerned with quick tanning and drying of the part, and at the same time with maintaining the patient's body temperature. After I had tried many different methods and various types of apparatus, the following was gradually evolved.

The patient is completely undressed and placed in a bed with overhead bows or a cradle, over which are placed sheets and a light blanket. Two 60 ampere electric light globes are

Fig. 1—Exterior view

Fig. 2—Interior view showing construction. The covering is sheet metal covered with asbestos.

suspended within to maintain a constant temperature. After each hourly spraying, the nose of the air-blower is put under the covering at the foot of the bed and a current of warm air is gently circulated about the patient. This is allowed to continue about twenty or thirty minutes.

The blower is of value in drying out wounds which, owing to nature or location, are causing maceration of the surrounding skin, such as decubitus ulcers, ectrophy of the bladder or small

intestinal fistulas. The accompanying illustrations show clearly the simplicity of its construction, and I believe that it can be readily made by any tinsmith or electrician.

Osler Building

## A LARGE TERATOMA CONTAINING RUDIMENTARY ARM BONES AND A HAND

R. J. BRINES, M.D., YENCHENG, HONAN, CHINA

A man, aged 24, a farmer, came to the outpatient clinic in August 1932 for the treatment of a large tumor on the left buttock, which had increased in size gradually since birth. The man was well developed and healthy. When surgical removal was advised he became frightened and returned home. After some correspondence he was encouraged to return, and, March 2, 1933, the tumor was removed without any surgical difficulties being encountered. Large reflected skin flaps were sewed over the denuded area to which the tumor had been attached. Convalescence was uneventful.

The tumor weighed 31 pounds (14.1 Kg) and was firmly attached at one side to the coccyx by dense fibrous tissue. The remainder of the anterior side was loosely attached to the gluteal region. Bones could be felt along the entire posterior medial side of the tumor. A ball-like mass protruded from the upper lateral side. This part contained about 3 pounds (1,300 Gm) of sebaceous material and was connected to the main cavity by a small canal plugged with the same material.

After removal the tumor was opened on its anterior, soft, surface. It contained about 12 quarts (liters) of dark, cloudy fluid in which there were floating many balls of sebaceous material about one-half inch in diameter. Four balls of hair thickly matted together about 2 inches in diameter were found, also several long pieces of finger nails, but no other objects.

Firmly attached to the coccyx by dense fibrous tissue was a short bone, which was directed posterolaterally and articulated by a normal joint with a 14 inch bone that extended downward along the posteromedian side of the tumor. This bone was thick and flat and in its lower half there existed a pseudo-arthritis, probably due to an old fracture. A spur of bone extended upward and anteriorly from the lower end of the long bone. At the upper end of this spur were seen several rather irregular metacarpal bones, and attached to these distally were well formed phalanges. This condition was revealed by roentgen examination.

The interior of the tumor was covered with a thin white skin on which was growing sparsely long black curly hair. Protruding from the lower medial surface of the tumor into the large cavity was a definitely formed hand, with its palmar surface directed posteriorly. The thumb of the hand was about of normal size and bore a small supernumerary digit. This part was easily movable and bore a thumb nail. The next three fingers were absent, and long curled finger nails about an inch and a half in length were attached to the body of the hand. A small little finger was found at the side of the hand. It was freely movable and had a small nail. Study of this tumor as a whole, together with a roentgenogram, clearly revealed the fact that an extra upper extremity had developed to quite a degree of perfection in this large teratoma.

The Yencheng Sanitarium-Hospital

Patient with teratoma. He could not sit in an ordinary chair since the tumor extended so far back that it alone filled the seat.

<sup>4</sup> Bullowa, J. G. M. and Gottlieb, C. Roentgen Ray Study of Bronchial Function. *Am. J. M. Sc.* 160: 98 (July) 1920.

## Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY OF THE AMERICAN MEDICAL ASSOCIATION HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS  
H A CARTER Secretary

### SPECIALISTS' MODEL SOLLUX RADIANT HEAT LAMP ACCEPTABLE

The Hanovia Chemical and Manufacturing Company claims that this unit is particularly adapted for ear and throat work or for local application of radiant heat. The lamp employs a 300 watt tungsten filament bulb. It is said to be effective in ear conditions and aids cessation of discharge.

The Specialists' Model Radiant Heat Lamp comes in two styles: the stand type and the desk type.

In an investigation carried out in a laboratory acceptable to the Council, it was found that on 109 volts the current read 235 amperes. On 118 volts it was 254 amperes. The height of the stand model examined when extended was 54 inches. The Specialists' Model Sollux Radiant Heat Lamp is included in the Council's list of accepted devices.

Specialists Model Sollux Radiant Heat Lamp

### HOSPITAL MODEL SOLLUX RADIANT HEAT LAMP ACCEPTABLE

The Hanovia Chemical & Manufacturing Company recommends this unit for use in a physician's office or a general hospital. The heating element may be either a 1,000 watt tungsten filament incandescent bulb or a 1,000 watt Hanovia unit, consisting of four wire wound refractory rods set at 90 degrees from each other. The resistance coils are 7 inches long and are connected in parallel. The terraced aluminum reflector hood, 18 inches in diameter, is said to provide a uniform field for both the metallic resistor and the tungsten incandescent bulb.

The firm claims that at a distance of 48 inches with an area coverage 5 feet in diameter, points on a plane surface perpendicular to the primary direction of the rays will experience intensity deviations of less than 20 per cent. At a shorter distance, e.g., 24 inches, with an area coverage 3 feet in diameter, such a plane surface will have intensity deviations of less than 10 per cent.

In a laboratory test the 1,000 watt resistance unit was connected to an alternating current line of 107 volts, and the current read 875 amperes. At a distance of 30 inches from the edge of the reflector (wire screen attached) and within an area formed by a 2 foot (diameter) circle directly in front of the reflector on a plane perpendicular to the center rays, the energy values measured by a thermopile and galvanometer substantiated the claims of the manufacturer.

The stand has a height of approximately 6 feet and may be adjusted between 72 and 42 inches. All of the parts except the four legged black flaked base are either polished aluminum or nickel finish. The reflector unit and the burner are counterbalanced, providing easy adjustment.

The hood may be set in any position—either vertically or horizontally. Large and small localizing cones and a straight telescopic localizer are available for use with this lamp.

The Hospital Model Sollux Radiant Heat Lamp therefore, is included in the Council's list of accepted devices.

Hospital Model Sollux Radiant Heat Lamp

### OFFICE MODEL SOLLUX RADIANT HEAT LAMP ACCEPTABLE

The Hanovia Chemical and Manufacturing Company declares that this unit has been designed to provide the physician and the specialist with a moderately priced office infra-red lamp of exceptional flexibility and therapeutic efficiency.

The light element consists of a 500 watt tungsten gas-filled glass bulb or a 500 watt wire wound infra-red generator, both of which are interchangeable in the lamp. The terraced reflector hood is spun from heavy gaged aluminum, highly polished on the outside and having a brush finish on the inside. In conjunction with the terraced reflector, the interior brush finish is said to be most effective in diffusing the infra-red rays over a wide area. The diameter of the reflector is 14 inches. A wire screen can be provided, if desired.

The reflector cross arm member extends the hood 30 inches from the telescopic upright. The vertical adjustments can be made from 36 inches to about 62 inches from the floor. There is a combination of two swivel bearings, enabling the hood to be adjusted in practically any position. The upright is mounted on a three legged castiron base.

In a laboratory test it was found that, by connecting the Mazda 500 watt lamp to an alternating current line having an electromotive force of 109 volts, the current read 421 amperes, and on a 118 volt line the current read 423 amperes. At 30 inches, which appeared to be a comfortable distance between the patient and the lamp, the relative radiant energy values were noted. With a thermopile, it was found that, within an area covered by a 24 inch circle on a plane (in air) perpendicular to the direction of the center rays, the radiant energy in the center was from 25 to 30 per cent greater than that of the periphery.

In a clinic acceptable to the Council, this unit was tried and found to give satisfactory service. The Office Model Sollux Radiant Heat Lamp, therefore, is included in the Council's list of accepted devices.

Office Model Sollux Radiant Heat Lamp

### BURDICK DUAL ZOALITE ACCEPTABLE

The Burdick Corporation, Milton, Wis., declares that this unit was developed and designed to provide a source of infra-red to meet every treatment condition for which infra-red radiation is indicated. The resistance unit is a cylinder made of ceramic material, in which resistance wire is embedded. The current being turned on, the ceramic material heats to a cherry red. The heating unit is placed approximately at the focal point of the nickel plated reflector. The opening of the reflector is 9 inches in diameter, and a wire screen is fitted over it. On the back of the larger unit, a small localizing unit is mounted, their reflectors facing opposite directions. The firm claims that by means of this localizing unit it is no longer necessary to heat the entire head when applying infra-red to the ear or other localized area around the head.

The unit was examined in a physical laboratory. When the large unit was connected to a 112 volt alternating current line the current reading was 32 amperes. On 120 volts the current read 343 amperes. The small unit is rated at 75 watts. On a 119 volt alternating current line it drew 0.6 ampere. At 117 volts the current was 0.64 ampere. Irradiating a plane area of 2 feet in diameter (in air) perpendicular to center rays at 40 inches from the reflector of the larger unit, the intensity at the center of the area is more than twice the energy at the edges. Within an area of a circle 1 foot in diameter, directly in front but 40 inches from the reflector, the radiant heat intensity at the center was 36 per cent more than the intensity on the periphery of the same area.

Burdick Dual Zoalite

The unit is mounted on an enamel base. When the upright is fully extended, the distance of the lamp from the floor is 7 feet. There is an extension range of 2 feet 6 inches. The reflector and heating unit may be placed in almost any position by virtue of the flexible gooseneck arm supporting it. The current is supplied by means of a cord on which is placed a dual switch. The two units may be operated separately or together. The Burdick Dual Zoalite, therefore, is included in the list of accepted devices.

## Council on Pharmacy and Chemistry

### NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS JEECH, Secretary

**CAROTENE-SMACO**—A mixture of crystalline isomeric hydrocarbons extracted from carrots. The empirical formulas may each be represented as  $C_{40}H_{56}$ . One of the isomers designated as  $\alpha$ -carotene is reported to be optically active,  $[\alpha]_{20}^{25}/\text{Cd}$  in benzene = +380. The other, designated as  $\beta$ -carotene, is optically inactive. The mixture contains approximately one part of  $\alpha$ -carotene and four parts of  $\beta$  carotene. The crystals are easily oxidized. They should be kept in a vacuum or under an inert gas in the dark at a low temperature. The international unit for vitamin A is determined by the potency of 1 microgram of a mixture of carotenes and is equivalent biologically to 1 unit of vitamin A as defined for Cod Liver Oil—U S P X-Revised, 1934. Carotene-SMACO is claimed to be a purer product than the International Standard carotene and therefore more active.

**Actions and Uses**—The evidence indicates that carotene is converted in the liver into vitamin A. Carotene therefore has actions similar to those of vitamin A. As carotene is a mixture of the alpha and beta forms its relative efficiency may vary according to the ratios of those two components. Evidence is not yet available on which to base an exact conversion factor of carotene in terms of clinical vitamin A effect. Much depends on the conditions for absorption of the pigment. In view of the fact that cases of carotenemia have arisen from overdosage, the Council warns against the administration of too large doses of carotene.

**Dosage**—The dosage of carotene or vitamin A is not yet on a satisfactory basis. Based on the average daily dose of Cod Liver Oil—U S P X-Revised, 1934 (three teaspoonfuls, 12 cc) the dose should be equivalent to at least 6,624 U S P X-Revised, 1934, units. Carotene is generally administered in the form of carotene dissolved in an oily solution. Solutions of carotene may decompose unless there is present an inhibiting substance, either an extract from carrots or a chemical inhibitor.

Manufactured by the S M A Corporation, Cleveland, Ohio. No U S patent or trademark.

Carotene SMACO occurs as crystals which in plain light show cleavage in two directions and which are pleochroic: light yellow orange to dark yellow orange to dark orange. In polarized light they are anisotropic: biaxial with parallel extinction and medium low birefringence. The crystals are almost tasteless and have a slight aromatic odor. They are soluble in chloroform and benzene slightly soluble in ether, petroleum ether, fats and oils, very slightly soluble in alcohol, practically insoluble in water. (Carotene SMACO as marketed is not completely soluble in petroleum ether.) Carotene SMACO melts between 172 and 178°C.

Dissolve about 0.025 Gm of carotene SMACO in 50 cc of chloroform. Mix 1 cc of this solution with 5 cc of a saturated solution of antimony trichloride in chloroform. A blue color develops in five minutes. Dissolve exactly 0.020 Gm of carotene SMACO in 2 cc of chloroform; dilute to exactly 100 cc with petroleum ether; dilute 1 cc of this solution to exactly 100 cc with ethyl alcohol; measure the per cent transmittance of a 3 cm layer of this solution at the following wave lengths: 490, 500, 515 and 530  $\mu$ ; the per cent transmittance values are within the following limits: 490  $\mu$ , 12.17 per cent; 500  $\mu$ , 33.38 per cent; 515  $\mu$ , 75.81 per cent; 530  $\mu$ , 90.95 per cent.

Fuse about 0.1 Gm of carotene SMACO with metallic sodium; carefully add the fused residue to a beaker containing water; boil; filter; add 3 cc of ferrous sulphate solution; boil; add 1 cc of ferric chloride solution; neutralize the alkali with diluted hydrochloric acid; filter; no blue precipitate remains on the filter paper. (Nitrogenous compounds.)

Dry 0.1 Gm of carotene SMACO to constant weight over phosphorus pentoxide; the loss is not more than 0.2 per cent. Determine carbon and hydrogen by micro methods based on the dried material; the carbon is not less than 88.80 per cent nor more than 89.60 per cent and the hydrogen is not less than 10.30 per cent nor more than 10.80 per cent.

Incinerate about 0.10 Gm in a platinum dish; the residue is negligible.

The following colorimetric assay is a modification of Palmer's method. Carotene SMACO in petroleum ether is matched against 0.2 per cent aqueous potassium dichromate solution. By this method 40 mm of 0.2 per cent potassium dichromate solution is equivalent to 48 mm of 0.00268 per cent carotene SMACO solution. Transfer about 0.020 Gm of carotene SMACO to a 500 cc flask; dissolve the crystals in about 2 cc of chloroform; dilute with petroleum ether to exactly 500 cc and match this in a colorimeter with 40 mm of a 0.2 per cent aqueous potassium dichromate solution. Rapidly make five readings that do not vary more than 1.5 mm. Use the average reading in the following formula and calculate the per cent of carotene SMACO.

$$\frac{0.1287 \times 500}{\text{average weight of sample}} = \text{per cent carotene SMACO}$$

The carotene SMACO is not less than 92 per cent.

**SMACO Carotene in Oil**—A solution containing 0.3 per cent of carotene-SMACO in cottonseed oil. It is biologically assayed to have in each gram a vitamin A potency of not less than 7,500 units, U S P X-Revised, 1934.

**Actions and Uses**—The same as those of carotene SMACO.

**Dosage**—See under Carotene-SMACO. The product as marketed is accompanied by a dropper designed to deliver 25 drops to the cubic centimeter.

Manufactured by the S M A Corporation, Cleveland, Ohio.

SMACO carotene in oil is prepared by dissolving in cottonseed oil carotene SMACO with an extract of carrots containing an antioxidant. The solution is standardized to 0.3 per cent of carotene SMACO by the method described under that product. The finished product is assayed for vitamin A potency by the method of the U S P X-Revised, 1934, to contain not less than 7,500 units per gram.

**SMACO Carotene with Vitamin D Concentrate in Oil**—A solution in cottonseed oil of carotene-SMACO 0.3 per cent with sufficient vitamin D concentrate to bring the assayed potency to not less than 1,000 U S P X-Revised, 1934, units per gram. It is assayed for vitamin A potency by the method of the U S P X-Revised, 1934, to contain in each gram not less than 7,500 units.

**Actions and Uses**—SMACO carotene with vitamin D concentrate in oil is proposed as a substitute for a cod liver oil of equivalent potency.

**Dosage**—The same as for cod liver oil of equivalent potency.

Manufactured by the S M A Corporation. The vitamin D concentrate is used by license of Columbia University under U S patent 1,678,454 (July 24, 1928, expires 1945). No U S trademark.

**SMACO Carotene and Vitamin D Concentrate in Cod Liver Oil**—A solution of carotene-SMACO, 0.03 per cent, in cod liver oil, adjusted by the addition of sufficient SMACO vitamin D concentrate so that it will assay at not less than 100 units of vitamin D, U S P X-Revised, 1934, per gram. The mixture is assayed to have a vitamin A potency of not less than 2,000 units U S P X-Revised, 1934, per gram. The Carotene-SMACO is the source of not less than 650 of these units.

**Actions and Uses**—SMACO carotene and vitamin D concentrate in cod liver oil is proposed for use as a substitute for cod liver oil of high potency.

**Dosage**—The same as for cod liver oil of equivalent potency.

Manufactured by the S M A Corporation, Cleveland. The vitamin D concentrate is used by license of Columbia University under U S patent 1,678,454 (July 24, 1928, expires 1955). No U S trademark.

**SMACO Vitamin D Concentrate in Oil**—A solution in cottonseed oil of the vitamin D concentrate of cod liver oil obtained by the method of Zucker. It is assayed to have in each gram a potency of not less than 1,000 units of vitamin D, U S P X-Revised, 1934.

**Actions and Uses**—SMACO vitamin D concentrate in oil is proposed for use as an antirachitic.

**Dosage**—Based on the average daily dose of cod liver oil U S P (three teaspoonfuls, 12 cc), the dose should be equivalent to at least 930 units of vitamin D, U S P X-Revised, 1934. This is suggested as an approximate dosage. The product as marketed is accompanied by a dropper designed to deliver 25 drops to the cubic centimeter.

Manufactured by S M A Corporation, Cleveland. The vitamin D concentrate is used by license of Columbia University under U S patent 1,678,454 (July 24, 1928, expires 1945). No U S trademark.

**SMACO Carotene with Vitamin D Concentrate in Oil**—(See under Carotene-SMACO).

**SMACO Carotene and Vitamin D Concentrate in Cod Liver Oil**—(See under Carotene SMACO).

## Committee on Foods

### ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG Secretary

### CELLU JUICE-PAK BARTLETT PEARS

**Distributor**—The Chicago Dietetic Supply House Inc., Chicago

**Packer**—Eugene Fruit Growers Association, Eugene, Ore

**Description**—Processed, peeled and cored Bartlett pears packed in undiluted juice without added sugar

**Manufacture**—The pears are picked hard but when they have reached the required degree of firmness (determined by a pressure testing machine) are brought to the plant, graded, stored for ripening until soft and golden colored peeled by hand, spray washed, graded according to size halved, cored by hand, and packed in cans according to size and count. Between operations the fruit is kept in a 4 per cent brine solution to retard oxidation. The cans are filled with undiluted pear juice from pressed, sound off size fruit. The cans are placed in an exhaust box for a definite period at 91 C after which they are sealed, processed for a fixed time at 100 C, cooled and stored. Before shipment, the cans are inspected and labeled.

**Claims of Manufacturer**—Packed in undiluted pear juice without added sugar

### FISHERS PANCAKE FLOUR

**Manufacturer**—Fisher Flouring Mills Company Seattle

**Description**—Pancake flour containing wheat flour, powdered skim milk, calcium acid phosphate dextrose sodium chloride and soda

**Manufacture**—The ingredients in formula proportions are thoroughly blended and packed in cotton bags. Baking tests are made on each batch run.

### (a) KRAFT'S RED RIBBON BRAND SPARKLING CRYSTAL WHITE SYRUP

### (b) KRAFT'S BLUE RIBBON BRAND SPARKLING GOLDEN SYRUP

**Distributor**—Henry Kraft Mercantile Company Nevada Mo

**Packer**—Bliss Syrup and Preserving Co, Kansas City, Mo

**Description**—(a) A table syrup corn syrup sweetened with sucrose syrup and flavored with vanilla.  
(b) A table syrup corn syrup flavored with refiners syrup.  
**Manufacture**—(a) The same as Bliss Pancake Crystal White Brand Syrup (THE JOURNAL Nov 18 1933 p 1635)  
(b) The same as Bliss Pancake Brand Golden Syrup (THE JOURNAL, October 28 1933 p 1393)

**Claims of Manufacturer**—Recommended for use as an easily digestible and readily assimilable carbohydrate supplement to milk in infant feeding and as a syrup for cooking, baking and the table.

### McCORMICK'S BEE BRAND CAKE & PASTRY SPICE

**Manufacturer**—McCormick and Company, Inc, Baltimore

**Description**—Spice mixture for use in cake and pastry baking, including nutmeg, allspice, cinnamon, ginger, cloves, coriander seed and caraway seed

**Manufacture**—Definite proportions of the spice ingredients, prepared as described under McCormick's Bee Brand Allspice (THE JOURNAL, Oct 28, 1933, p 1393), are mixed and automatically packed in tins

**Bottlers**—(2) Dairies Inc St Louis, (12) Franklin Co Operative Creamery Association, Minneapolis

**Description**—Bottled pasteurized milk fortified with vitamin D (vitamin D concentrate prepared from cod liver oil), contains 400 U S P X (Revised 1934) vitamin D units per quart

**Preparation**—The milk complies with legal requirements and is pasteurized by the standard holding method. See THE JOURNAL, July 1, 1933, page 34, for description of fortification with vitamin D

**Vitamins**—The vitamin D concentrate used and the fortified milk are regularly tested biologically. Clinical investigation shows this milk to be a reliable antirachitic agent if proper amount is used

**Claims of Distributors**—A vitamin D fortified antirachitic pasteurized milk having otherwise the flavor and food values of usual pasteurized milk

### FAIRY QUEEN SELF-RISING FLOUR (BLEACHED)

**Manufacturer**—The Light Grain and Milling Company, Liberal Kan

**Description**—Self-rising flour prepared from bleached hard winter wheat standard patent flour calcium acid phosphate sodium chloride and sodium bicarbonate, the same as Light's Best Oven Perfect Flour, Self-Rising (Bleached) (THE JOURNAL April 28 1934 p 1384)

## AMERICAN BRAND GOLDEN SYRUP

*Manufacturer*—American Syrup & Sorghum Company, St Louis

*Description*—Table syrup, corn syrup base (85 per cent) with refiners' syrup (15 per cent), seasoned with salt

*Manufacture*—Corn syrup, boiling refiners' syrup, hot water and a small amount of salt are mixed in definite proportions to produce a syrup of desired density. The syrup is heated to 82 C and packed in friction top cans

*Analysis* (submitted by manufacturer) —

(calculated from separate analyses of component syrups and formula of preparation)

	per cent
Moisture	25.9
Ash	0.8
Fat (ether extract)	0.0

No methods are available for accurately determining the composition of syrups of this nature, therefore the foregoing analysis is roughly approximate

*Calories*—2.9 per gram 82 per ounce

*Claims of Manufacturer*—Recommended for use as an easily digestible and readily assimilable carbohydrate supplement to milk in infant feeding and as a syrup for cooking, baking and the table

EXCELSA MUSHROOMS—FANCY BUTTONS  
EXCELSA MUSHROOMS—PIECES AND STEMS  
EXCELSA MUSHROOMS—SLICED

*Distributor*—Illinois Mushroom Co., Denver, Colo

*Packer*—Michigan Mushroom Company, Niles, Mich

*Description*—Cooked mushrooms, whole, sliced, or pieces and stems, with added water, salt, and citric acid (U S P)

*Manufacture*—Mushrooms are cultured on trays in a thin layer of rich top soil covering a mixture of dirt, lime straw and manure, in dark mushroom houses the temperature of which is controlled. The mushrooms are picked by hand, conveyed to the cannery, inspected (spots and dirt removed) and either mechanically sliced for "sliced mushrooms" or "pieces and stems" or automatically sorted to be canned as "buttons." All the mushroom material is carefully washed with water

The mushrooms, in perforated aluminum kettles, are immersed for one minute in a solution containing citric acid and salt, for from two to three minutes in water maintained at 88 C for the purpose of shrinking, and then in cold water for ten seconds. The drained material is weighed into cans, covered with hot salt solution, the cans are automatically capped, cooked in a steam retort at 116 C for twenty minutes and rapidly cooled with cold water

*Analysis* (submitted by manufacturer) —

	Mushrooms per cent	Drained Liquor per cent	Composite of Mushrooms and Liquor per cent
Moisture	89.0	95.3	92.3
Ash	1.4	1.5	1.4

Crude fiber	0.9	0.0	0.4
Carbohydrates other than crude fiber (by difference)	4.8	2.0	3.4

*Calories*—Mushrooms have little caloric value

## KEYSTONE EVAPORATED MILK

*Distributor*—Keystone Grocery Company, Inc., Harrisburg, Pa

*Packer*—The Page Milk Company, Merrill, Wis

*Description*—Canned unsweetened sterilized evaporated milk, the same as Page Brand Evaporated Milk (Sterilized, Unsweetened), *THE JOURNAL*, May 30, 1931, page 1872

## Special Article

## ACUTE ANTERIOR POLIOMYELITIS

A REPORT ON THE FIRST PHASE OF THE  
1934 OUTBREAK

J C GEIGER, MD

GEORGE H BECKER, MD

AND

J P GRAY, MD

Director of Public Health Director of Bureau of Communicable  
Diseases and Assistant Director of Public Health  
Respectively City and County of San Francisco  
SAN FRANCISCO

With an elevation in the reported incidence of acute anterior poliomyelitis in California during the last spring and early summer months of 1934, the attention of public health officials has been attracted again to an outbreak on the Pacific Coast because of the apparent mutation of certain epidemiologic characteristics of the disease. This analysis of the San Francisco series of cases, reported during the months of May, June and July of 1934, is presented as a brief study of the first phase of the outbreak and because it is apparent that there is sufficient interest in the occurrence to warrant a preliminary report

Attention has been directed previously to the epidemiologic aspects of acute anterior poliomyelitis in California and in San Francisco,<sup>1</sup> but brief reference may not be inappropriate here. The disease has been given the label "infantile paralysis," has been described as one occurring more particularly in rural population groups, in some areas at least, and has been thought of as appearing usually during the late summer and early fall months. In California, however, it should be recognized that acute anterior poliomyelitis has affected individuals of nearly all age groups, even into the seventh decade, paralyzing not in every instance and leaving permanent residual paralysis in a relatively low percentage of the actual total number of cases, it might be called more appropriately a "disease of civilization," since its incidence in the urban population groups is the rule rather than the exception, and it has made its appearance in all the twelve months of the year, with an incidence elevated over that expected as a normal,<sup>2</sup> as early as April and as late as February and March

## SEASONAL INCIDENCE

A tabulation of the reported incidence of the disease by months over a period of years (1910-1934) demonstrates that acute anterior poliomyelitis occurs in San Francisco with a rather regular periodicity, with a cycle of from two to four years. In the series referred to, while it is apparent that there was an increase in the reported incidence consistently in alternate years during the decade 1911-1920, during this period the elevation reached a sufficiently high level to be considered what might be termed an outbreak only in 1916, when thirty-one cases were reported. It is to be remembered, however, that the diagnosis of acute anterior poliomyelitis at that time was more truly that of "infantile paralysis," and on this basis it is reasonable to assume that there were many other individuals affected by the

1 Geiger J C and Gray J P. A Statistical Analysis of the Outbreak of Acute Anterior Poliomyelitis in San Francisco in 1930 *J Prev Med* 6 145 (May) 1932

2 The normal referred to is based on the average nonepidemic reported incidence week by week over a ten year period corrected to population estimates

disease, in whom paralysis, or even paresis, did not occur, and whose illnesses therefore were not reported and probably in many instances not even seen by a medical attendant. During the decade 1921-1930, moreover, the periodicity, while apparently less regular, continued with definitely increased numbers of reported cases in successive outbreaks, as in 1921 (60 cases), 1925 (66 cases), 1927 (90 cases) and 1930 (230 cases).<sup>3</sup>

It is noteworthy also that the curve for reported cases in California by weeks in 1930 showed a definite second phase, believed to be due to the San Francisco series of cases. During the 1930 outbreak, the most extensive recorded in California until the outbreak of 1934, there was a period of latency of approximately two months between the definite indications of an increase in the number of cases of acute anterior poliomyelitis reported for California and that for San Francisco.

A study of the weekly reports of the *Bulletin of the State of California Department of Public Health* reveals the fact that the first indication of a definite increase in the reported incidence of acute anterior poliomyelitis in California in 1934 occurred during the last week of April and the first weeks of May. Most of the cases in the group referred to were located in the Los Angeles metropolitan area. In San Francisco the first instances in which the disease was suspected were reported during the last half of May, a circumstance which leads to the impression that the latent period between the appearance of the disease in the two population centers was materially shortened over that of 1930. This factor warrants interest because of the considerable amount of travel that takes place between the two cities. No explanation is offered for this apparent shortening of the latent period other than that it might be assumed that the two series of cases, in the Los Angeles area and in San Francisco, were unrelated in 1930, and that there is a relationship, approaching simultaneity, in 1934. With a detailed study of the dates of onset of the series of cases in the two communities, more nearly accurate epidemiologic data will be available.

#### PLANS FOR OUTBREAK

With the rapidly increasing reported incidence of acute anterior poliomyelitis in southern California and the appearance of the first cases in San Francisco in May, the director of public health invited a group of San Francisco men to sit on the Committee on Acute Anterior Poliomyelitis,<sup>4</sup> to serve in an advisory capacity to aid him in laying plans for the expected outbreak. The committee was made up of representatives of the Hooper Foundation for Medical Research, of the faculties of the University of California and Stanford University medical schools, of the San Francisco chapter of the American Academy of Pediatrics, of the San Francisco County Medical Society, and, from official San Francisco, of the Health Advisory Board and of the Board of Supervisors (Health and Finance committees). Certain members of the staff of the Department of Public Health, in addition, attended the meetings of the committee. Among the group were public health administrators, bacteriologists, epidemiologists, pediatricians, orthopedists, internists, surgeons and hospital administrators.

Plans were formulated for the establishment of diagnostic-treatment centers in those hospitals known to be able to meet certain fundamental requirements, including trained personnel, laboratory facilities and equipment, particularly Drinker respirators, for the bleeding of donors and the preparation of pooled convalescent and normal adult serums under standardized procedure, and for orthopedic care in each instance in which paralysis or paresis occurred. All physicians of San Francisco were sent an informative and instructive letter and a reprint of the "Practical Suggestions on Poliomyelitis" of the Special Committee of the American Medical Association.<sup>5</sup> Money was made available with the approval of the chief administrative officer and the mayor, by action of the Board of Supervisors, providing for certain technical assistance, payment of blood donors, purchase of experimental animals and increased facilities in the San Francisco Hospital.

Through the communication to physicians, through the press and in medical meetings, the committee advised the use of convalescent serum for the treatment of the affected individual (50 or 100 cc intramuscularly or intravenously, as indicated), and the use of normal adult pooled serum, properly prepared under a standard procedure, for the possible protective value that it might give, in direct and close contacts, including physicians, nurses and interns in attendance, and possibly their children (20 cc intramuscularly, repeated monthly), or whole blood, preferably from both parents, in this group (direct contacts and the like), (50 cc intramuscularly). At no time did the committee recommend or encourage attempts at mass immunization of the entire adult, adolescent or child population groups. It was stressed in newspaper publicity, by radio broadcast, by public address and in telephone contacts that the subject of the use of the normal adult pooled serum as a prophylactic providing passive immunization against acute anterior poliomyelitis was still controversial, that the benefits to be derived were probable but that they could not be positively assured, and that, while the laboratory evidence supported the thought that passive protection was a probability, the experimental state had certainly not been passed. The committee and the director of public health advised that individuals rely on the advice of their own physicians. Administration of serum by the department of public health was strictly limited to the San Francisco Hospital personnel and those direct contacts who were unable to pay for private medical attendance. Certain of the practicing medical profession encouraged the administration of the serum as a prophylactic in all children of their practices, others denounced its use. It was and is believed, however, by the committee, that the opportunity offered in the 1934 outbreak of acute anterior poliomyelitis in California offers an excellent opportunity to obtain data that may be of value in determining the worth both of convalescent serum in the treatment of the disease and of normal adult pooled serum as a prophylactic possibly providing protection against infection.

#### FIRST PHASE 1934 OUTBREAK

The first phase of the 1934 outbreak in San Francisco, during which there were reported more cases (100) than in the entire outbreak of 1927 (90), presents certain features that are believed worthy of analysis at this time. The first instances in which

<sup>3</sup> Duration of outbreaks with dispersion of cases: 1916 July through January; 1921 June through November; 1925 April through December; 1927 April through December; 1930 June through February.

<sup>4</sup> The members of the Committee on Acute Anterior Poliomyelitis were: K. F. Neyer, Ph.D., W. P. Lucas, M.D., E. B. Shaw, M.D., H. K. Faber, M.D., I. W. Ward, M.D., L. E. Abbott, M.D., I. W. Thorne, M.D., and A. E. Schmidt, M.D.

<sup>5</sup> This useful pamphlet was reprinted and copies were furnished by the State of California Department of Public Health at no cost to local authorities.

acute anterior poliomyelitis was suspected were reported during the second half of May. The weekly reports, when presented in the form of a curve on the logarithmic scale, superimposed on the normal expectancy curve, show a definite elevation of the reported incidence in the twenty-first week (ended May 26, 1934), when three were recorded as against none expected. Had the following week brought no additional cases, the occurrence of the cases during the one week would have had little or no significance, even with a continuation of the outbreak in southern California, but with four cases reported during the twenty-second week (ended June 2, 1934), there was confirmation of the impression that this elevation of reported incidence was probably the first warning of an outbreak in San Francisco. Additional support for the prediction that an outbreak of acute anterior poliomyelitis would occur during the summer of 1934 was found in the history of previous outbreaks in San Francisco as referred to, particularly since the disease did not appear in epidemic form after a three-year interval (1933).

Although outbreaks of acute anterior poliomyelitis in San Francisco have had their apparent onsets as early as April (1925 and 1927), the peak of the outbreak, or of the first phase of the outbreak, has not been reached heretofore as early as June. The first phase of the 1934 outbreak in San Francisco is definite and clean cut, on the bases of dates of reporting and of onset, with decreases in the number of reported cases in San Francisco consistently through the twenty-sixth, twenty-seventh, twenty-eighth and twenty-ninth weeks.

Mention should be made also of the parallelism that exists in the curves plotted for the reported incidence in the state of California, Los Angeles County (including the Los Angeles metropolitan area), Los Angeles city as a separate series and San Francisco. In each instance the curves exhibit a large angle with the base line, indicating a sharp elevation in incidence. The curves for the state and for Los Angeles County apparently are practically coincidental during the twenty-first week, ended May 26, 1934, but the curve for the state series of cases does not show a coincidental drop with the fall in the curves for Los Angeles, both city and county, continuing on up to reach a peak of 345 cases reported during the week ended June 23, 1934, coincidental with the peak of the curve for the San Francisco series by date of reporting.

The curve plotted for the San Francisco series, by weeks, by dates of onset, lies to the left of the curve for the same series by dates of reporting, with the peak reached during the twenty-fourth week, but one week later than the peak of the curves for the Los Angeles series, both by dates of report and by dates of onset. These data indicate simultaneity, therefore, between the two series of cases.

#### IMPRESSIONS FROM CASE RECORDS

At this time, although 100 cases have been reported during the first phase of the outbreak, complete records are available in only eighty-four instances. The data from these records have been tabulated and the following impressions deduced:

1 Among the total of eighty-four cases there were eight deaths, a fatality rate of 9.5 per cent (not including two deaths in individuals brought in from outside points for treatment, in whom death occurred within eighteen and thirty-six hours thereafter). (These eight deaths comprise the total in the entire series thus far, so that the fatality rate is now 8 per cent.)

2 Males were more frequently affected than females, in a ratio of 1.25:1, but there was equal distribution of sexes in the local series of deaths, in a ratio of 1:1.

3 The age group 5-15 years included fifty-seven cases, or 71 per cent of the total number analyzed, and males predominate over females in all groups except that of 26 years and over, in which males were affected less frequently than females, in a ratio of 0.43:1.

4 Age groupings of deaths show that six of the eight deaths in the San Francisco series fall in the 5-15 year group, with one each in the under 5 year group and in the 16-25 year group. (The two additional deaths in individuals whose source of infection was nonlocal were of women aged 20 and 26 years.)

5 Tabulation of types of onset shows that the most frequent group of initial symptoms and signs were those referable to the nervous system (twenty-five). The frankly gastro-intestinal type of onset occurred twelve times, but the respiratory type, frequently stressed in descriptions of the disease, was uncommon in its occurrence, being reported but twice in the series. In those instances in which the onset was of a combined type, however, the neurologic-respiratory combination was most frequently reported (twenty-five).

6 Paralysis, of one or more types, occurred in thirty-four of the eighty-four cases, or in a ratio of 0.4:1, and, in an additional ten instances, muscular weakness occurred, but a total of forty of the eighty-four (or 0.48:1) showed no paralysis and no paresis. The ratio of the paralyzed individual to the total reported cases, by age groups, was highest in the 16-25 year group (0.75) in which nine of twelve were paralyzed, and lowest in the age group 26 years and over (0.2), in which two of ten were paralyzed.

7 The distribution and extent of paralysis in the thirty-four instances reported are widely varied, with most frequent involvement of both arms, both arms and both legs, both legs and combinations of these with other parts, a total of twenty-one for these types. The bulbar type was also rather frequent, with a total of seven affected.

8 An attempt was made to correlate the reported changes in reflexes (early) and cerebrospinal fluid cell counts with paralysis.

A In twelve instances, in eight of which cerebrospinal fluid counts were recorded and averaged 139 cells per cubic millimeter, the reflexes were considered normal, but paralysis occurred. In eight instances, exaggeration of the reflexes was noted, and the cerebrospinal fluid cell counts in the seven instances in which lumbar puncture was done averaged 193. In the two instances in which these diminished reflex reactions were noted, the cerebrospinal fluid cell count was recorded in but one, showing 100 cells. In the paralyzed group, cerebrospinal fluid studies were not made in eleven of the thirty-four instances, and in twelve instances there were no records of reflex reactions.

B From the records in the nonparalytic group of forty cases, it is seen that in thirteen instances cerebrospinal fluid studies were not made. In nearly half of the entire groups, or nineteen, reflex reactions are not recorded. If a cell count of less than 12 is to be considered as within normal limits, six of the twenty-seven counts made were normal. Normal reflex reactions are recorded with average cell counts of 50 in five of the nine in this group. (In two others there were markedly elevated cell counts of 240 and 327, and in the two remaining no puncture was done.) Exaggerated reflex

reactions were noted in eight individuals of this group, in three of whom cerebrospinal fluid cell counts were normal, but in five of whom the average was 300. In six instances, diminished reactions were noted, and in this group three cell counts were within normal limits, and three averaged 315.

C The data from the records in a third group of ten individuals in whom no paralysis occurred, but in whom muscular weakness or paresis or pain only were recorded, reveal high cell counts in three instances, a slightly elevated count in one, counts within normal limits in three, and no recorded studies in three. No apparent relation exists in this group between reflex reactions and cell counts.

9 In forty-nine of the eighty-four case records available, treatment included the intramuscular or intravenous administration of convalescent serum, convalescent plasma, immune sheep serum, immune horse serum, or whole blood transfusion. The group includes eighteen of the thirty-four paralyzed, twenty-five of the forty not paralyzed, and six of the ten whose disturbance included muscular weakness or paresis, or pain only.

A In the first subgroup, in six instances the immunotherapy was given on the same day on which the paralysis occurred, in four instances on the day preceding the onset of paralysis, in one instance on the second day before paralysis occurred, in five instances the date is not recorded, and in the other two instances the paralysis occurred on the sixth day of the disease but the report does not include the date of the administration of serum in one, and the serum was given during the day after paralysis had developed in the other. The time interval between the date of onset and the administration of immunotherapy was one day or less in four instances, two days in three instances, three days in two instances and from four to seven days in seven instances. In the remaining two instances the case records are incomplete.

B The same data for the nonparalyzed subgroup of twenty-five were as follows. Ten patients received immunotherapy during the first day following the onset of the disease, three patients received treatment two days following onset, treatment was delayed in four until the third day, and in four, the delay was of four or more days' duration. In four instances the records are incomplete as to dates of administration of serum.

C In the group exhibiting only pain or muscular weakness, six of the ten patients received immunotherapy after intervals of one day (one), three days (one), twelve days (one) and unrecorded intervals (three).

10 Of the entire group of eighty-four, seventy-four were hospitalized in eleven institutions.

11 In no instance in the series in which the case records are complete had tonsillectomy, when noted, been performed within a year. Of the twenty-six patients in whom tonsillectomy had been done one or more years previously, fourteen were paralyzed.

12 In five instances of the eighty-four, a definite statement was made that the patient had been swimming five, seven, nine, ten and fourteen days prior to the date of onset of acute anterior poliomyelitis. In four of the five, paralysis occurred.

#### SUMMARY OF ACTIVITIES DIRECTED AT THE CONTROL OF THE DISEASE

Among the measures that were initiated and carried out by the Department of Public Health and the Com-

mittee on Acute Anterior Poliomyelitis may be included the following:

1 The organization of the committee, composed of students of the disease, represented the various local units within organized medicine and the universities' medical schools.

2 The outline of policies to be followed in recommending the use of convalescent and normal adult pooled serum in the treatment of the disease and as a prophylactic against the infection.

3 The establishment of regulated diagnostic-treatment centers in local hospitals.

4 The regulation and supervision of those laboratories collecting, processing and distributing convalescent and normal adult pooled serums.

5 The dissemination of public health information through the public press and by radio broadcast, at frequent intervals.

6 The instruction of physicians by letter, pamphlet, hospital staff meetings, and general society meetings (one attended by more than 1,500 persons).

7 The execution of state regulations on quarantine of cases and direct contacts (three week period).

8 Epidemiologic study of each individual reported case by an epidemiologist (physician), and a follow-up epidemiologic study in those families in which cases or contacts were known to have developed, by a public health nurse.

9 Emphasis on the need for adequate orthopedic care for each and every patient in whom paralysis or paresis occurred, not only during the acute stages of the disease but throughout convalescence over many months, as indicated, and the provision for such care by the city and county of San Francisco for those who could not provide such care for themselves.

10 The continuation of school as in normal years, with the year ending as scheduled on June 15, 1934.

11 The nonclosing of swimming pools, since those who wished to swim were subjected to fewer dangers in well conducted pools than in polluted bay or ocean waters, but swimming was discouraged on the basis of the fact that flushing out of the nasopharynx disturbs the normal physiologic and biochemical protective mechanism that probably exists in a considerable proportion of the population.

12 The regulation of camps, with emphasis on the necessity for medical or nursing attendance at all times, for available isolation facilities, for a check-up examination on every child by a physician within twenty-four hours before he leaves for camp, and for the limitation of membership in each camp to children from the same or neighboring communities in which similar incidence of the disease obtained.

#### CONCLUSION

Acute anterior poliomyelitis has occurred in San Francisco in 1934 to an extent not heretofore recorded for this community so early in the year. Two courses exist as possibilities that may be expected during the coming weeks. (1) The first phase, which is analyzed in this paper, will be followed by a second phase, which may see an even greater elevation of the reported incidence of acute anterior poliomyelitis, with the peak reached in August, September or even October, and (2) the first phase may represent the entire outbreak, which would be an epidemiologic hybrid, manifesting another of the protean forms which outbreaks of this disease present in California.

## "SMOOTH" vs "ROUGH" TYPHOID VACCINES

In an examination of six stock cultures used for the commercial preparation of typhoid vaccines, Larkum<sup>1</sup> found but one culture of typical virulence and cultural characteristics. In a similar survey, Grinnell<sup>2</sup> reported that twelve stock strains of *Bacillus typhosus* used by different commercial laboratories differed from recently isolated typhoid strains not only in cultural characteristics and virulence but also in protective efficiency for laboratory animals. Most of the atypical strains thus reported were "rough" variants of the conventional "smooth" type of *Bacillus typhosus*.

Observations of this type have been quoted as probable explanations for the numerous failures of routine typhoid vaccines to afford adequate protection against subsequent exposure to a typhoid epidemic. This assumed inefficiency of "rough" vaccines was confirmed about four years ago by Grinnell<sup>3</sup> of the Harvard Medical School, who made relative efficiency tests on human subjects. He found that the customary course of vaccination with a typical, smooth, virulent strain of *Bacillus typhosus* led to a definite increase in the normal specific bactericidal power of human blood serum. Control vaccinations with atypical, "rough," avirulent "dis-sociates" of the same strain led to little or no increase in normal bactericidal titer. It appeared logical to assume from his observations that "rough" typhoid vaccines are valueless in clinical prophylaxis.

There has been rapidly increasing evidence during the last four years that in many specific infectious diseases the specific antibody titer of the blood serum is not a reliable index to individual immunity. In some cases, adequate tissue immunity is known to exist in the absence of demonstrable circulating antibodies. In other cases, high "antibody" titer may be demonstrated in individuals highly susceptible to homologous infections.

Maltaner<sup>4</sup> of Columbia University has recently retested the relative efficiency of "smooth" and "rough" typhoid vaccines, using experimental methods that would test both humoral and cellular immunities. Using sufficiently large intravenous doses of a highly virulent typhoid culture, for example, the New York investigator found that fully 80 per cent of all injected normal rabbits died in about twenty-four hours from acute toxemia. In his hands the "rough" and "smooth" typhoid vaccines were equally effective in preventing this acute death, cutting down the 80 per cent mortality to 15 and 13 per cent, respectively. After intravenous injection of his routine test dose, *Bacillus typhosus* could be demonstrated in the bile of many rabbits. The date of his examinations varied from several days to several weeks after the injection. In a series of fifteen normal rabbits, fourteen (93 per cent) developed this bile carrier condition. This percentage was reduced to 40 as a result of previous vaccination with a typical "smooth" typhoid vaccine. Much to his surprise, previous immunization with the "rough" vaccine was even more efficient and reduced the carrier percentage to 13. If one dare assume that prevention of this carrier condition in rabbits is a reliable indication of probable clinical value, one is forced to conclude that "rough," "atypical" or "involution" forms of *Bacillus typhosus* are the cultures of choice for the preparation of routine vaccines.

The main interest in the Grinnell-Maltaner controversy is to call attention to the contradictory conclusions that may be drawn from different arbitrary technics on lower animals. None of these technics reproduce the exact conditions of human epidemiology. Although no final conclusion can be drawn from such data, a clinical trial of a polyvalent antityphoid vaccine containing both "rough" and "smooth" types seems indicated.

## HEAD INJURY AND POSTTRAUMATIC NEUROSIS

For many years medical opinion regarding the late symptoms of head injury has oscillated between the organic and the functional points of view. Although the debate has been concentrated for the most part among the neurologists and psychiatrists, the frequency of concussions of various sorts makes the problem important to all physicians. Current reports indicate that the question is far from settled.

Strauss and Savitsky,<sup>1</sup> while recognizing the psychiatric factor in some cases of head injury, champion the organic explanation. They deplore the tendency of some examiners to ignore unfamiliar changes and unusual clinical observations by relegating them to the vague group of "functional" manifestations. Too much emphasis, they believe, has been placed in the past on

1 Larkum N W Michigan Department of Health Reprints Series No 56 1929  
2 Grinnell F B J Exper Med 56 907 (Dec) 1932  
3 Grinnell F B J Immunol 19 457 (Nov) 1930

4 Maltaner F J Immunol 26 161 (March) 1934  
1 Strauss Israel and Savitsky Nathan Head Injury Arch Neurol & Psychiat 31 893 (May) 1934

the necessity for the presence of intellectual defects in cases of organic disease of the brain. The term "traumatic neurosis" should be reserved for the terror and anxiety reaction following a threat of bodily injury. The subjective posttraumatic syndrome, on the other hand, characterized by headache, dizziness, inordinate fatigue on effort, intolerance to intoxicants and vasomotor instability is, they feel, organic, and dependent on a disturbance in intracranial equilibrium due directly to the blow on the head.

This opinion is not based on the results of the usual neurologic examination or "normal" mental status. A systematic clinical survey, utilizing some of the newer methods of examination and the cooperation of several investigators, has led the authors to this conclusion. The extensive distribution of the visual pathways and the position of the visual centers in the occipital lobes expose them to involvement during head injury. Extensive defects in the fields can, in fact, exist without any complaint. Careful ophthalmologic studies including the visual fields should therefore be made. The suggestion that ring scotomas may be due to fatigue is worthy of close scrutiny, since fatigue and ready exhaustion run through the whole clinical picture of the postconcussion state. A prominent mode of expression of a diseased brain may, indeed, be ready fatigue. It is not reasonable to maintain, however, that the only mechanism of this fatigue is ideogenous. While constriction of the visual fields may be an expression of functional disease, it occurs at other times as a definite manifestation of organic defect or injury. Vestibular tests with accurate determinations of auditory acuity should also be made. Involvement of the ear or labyrinth before the accident should, if possible, be ruled out.

Considerable emphasis is placed by the New York investigators on encephalography as a mode of examination. Despite the absence of normal controls it is their impression that physiologic variants of the contour of the ventricles and the subarachnoid space are rare, and that, given a good technic, certain well known changes on the roentgenogram indubitably point to the existence of some degree of previous or present intracranial damage. With these accessory methods of diagnosis they believe it possible to demonstrate organic abnormalities in a large number of patients with postconcussion symptoms. In any case something will have to be done in the near future, they believe, to minimize the number of unjust rewards and unfair rejections of claims for compensation resulting from head injuries.

Hall and Mackay,<sup>2</sup> taking issue to some extent with the "organic" conclusions of Strauss and Savitsky, call attention to the fact that the neuroses following injury to the head do not differ materially from those after injury to other parts of the body, in which injury to the central nervous system cannot be in question. It

seems unwarranted, consequently, to abandon the concept of neurosis following head trauma. The term "neurosis" is no longer a waste basket for diagnostic failure but is recognizable by a definite symptomatology. The majority of these neuroses fall into one of three groups: posttraumatic neurasthenia, posttraumatic anxiety neurosis or posttraumatic hysteria. Furthermore, these workers seriously question the value of the encephalogram in elucidating the question of organic brain disorders due to trauma, since they point out that what constitutes a normal encephalogram has not been finally established.

Two schools of thought concerning the effects of head injury are thus seen to be developing. Each acknowledges the contributions and part played by the other, their differences are in part only differences of emphasis. Interlocking factors are recognized by both, and the question to determine seems to be primarily whether the concussion produces organic disturbances of the central nervous system with resultant "functional" symptoms or whether it acts as the precipitating factor in a person already prone to a neurosis.

#### A DIETARY QUACK DISCUSSES DYSENTERY

Since amebic dysentery began to attract wide public attention, every popular writer on health has discussed the disease in a newspaper or periodical. These discourses have demonstrated not only a considerable amount of wisdom but also some of the most extraordinary conceptions conceivable by the mind of man. The apotheosis of nonsense would seem to have been reached in a statement put forth by Frank McCoy, whose record has been made available both in *THE JOURNAL* and in *Hygieia*. Since his medical training included only the study of chiropractic and physical culture, his views regarding diseases of bacterial or parasitic origin are bizarre and amusing. With the usual ignorance and perverted reasoning powers of those who oppose the established facts of science, he insists that the amebas are the result and not the cause of dysentery. Thus his statement reads:

'Acute diarrhea is usually produced by some kind of food poisoning, and may occur several days after one has eaten sausage, canned fish or other foods which sometimes produce ptomaine poisoning. The frequent bowel movements are simply Nature's way of trying to get rid of some offensive poisonous substance.

"If such an acute attack occurs, it may be rapidly cured by the use of two or three enemas, taken one hour apart. This simply gives the colon more water with which to wash out the irritating material.

Chronic diarrhea often turns into a condition called dysentery, with many bowel movements each day. These movements frequently contain large quantities of mucus and small amounts of blood. A careful examination of this discharge will disclose the presence of small single-cell forms of life called amoeba.

'The common belief is that these amoeba produce the dysentery and much effort is made to kill them off by strong enemas and the administration of such remedies as emetin. In fact as in many cases of medical practice, it is like 'putting

<sup>2</sup> Hall, G. W. and Mackay, R. P. *The Posttraumatic Neuroses*. J. N. A. 102: 510 (Feb. 17) 1934.

the cart before the horse,' as the amoeba are the result and not the cause of dysentery

"In all dysentery, there will be found an extreme irritation of both the small and large intestines. This is produced by the throwing out from the liver of excess quantities of bile.

"As in acute forms of diarrhea, Nature is trying to throw out some offending substance. In the case of chronic dysentery, the offending poisons are being eliminated from the liver, itself.

"The only sensible course to follow is to stop all food for a week or two and allow the liver to completely empty out the toxic material. Two or three enemas should be used each day during the fasting treatment, and skin elimination increased by sponge or shower baths.

"I have handled the worst kind of cases of dysentery, and have never seen a case that could not be stopped by this treatment. If you or any of your friends have this trouble develop use this common sense method and see how quickly you can get over your trouble."

The danger to the public health of this type of advice is obvious. When one case of amebic dysentery appears in a family, other members are likely also to be infected unless suitable precautions are taken. Amebic dysentery treated by such methods as McCoy advocates is likely to result in serious complications if not fatally. Moreover, the food handler with amebic dysentery may menace an entire community. And like all the naturopathic, drugless and peculiar healers, McCoy joins the promoters of the colon-washing and filling stations.

How long will newspapers and periodicals which share some responsibility for the public health continue to advise the uninformed in regard to infectious diseases in such ways as to encourage the spread and the virulence of these infections? It is not known how many newspapers print these daily discourses of Frank McCoy, pet of the *Los Angeles Times*. Surely editors fail their readers when they continue to promulgate such superlative nonsense as emanates from McCoy and his *Los Angeles Times* associates.

## Current Comment

### REMOVAL OF CYSTS OF ENDAMOEBA HISTOLYTICA FROM WATER BY FILTRATION

The possibility of an outbreak of amebic dysentery as the result of a contaminated public water supply was emphasized by the outbreak that originated in Chicago last year. As the wide distribution of *Endamoeba histolytica* through the water supply was an unusual circumstance, experiments have been undertaken by Chicago investigators<sup>1</sup> to learn whether such parasites can be removed from water by the simple method of filtration. These experiments were conducted at the Chicago Experimental Filtration Plant. Suspensions containing a large number of cysts of *Endamoeba histolytica* from infected persons were mixed with clear water, treated with aluminum sulphate and then filtered through rapid sand filters. The filter bed used had the same depth,

and the size of the sand was the same as that found in many filtration plants throughout the country. The filters were operated at a rate of two gallons per square foot per minute, which is customary in filtration practice. The water, after being coagulated with aluminum sulphate, was agitated for fifteen minutes to form a good coagulum, and the coagulated water was then either filtered directly or allowed to stand thirty minutes and a large part of the sediment siphoned off, or it was siphoned from one receptacle to another without removal of the sediment. Beneath the 24 inches of sand in the filters were 8 inches of gravel, ranging in size from three-fourths inch in diameter at the bottom to one-eighth inch at the top. These filters had been used for months prior to these experiments, filtering coagulated Lake Michigan water. After filtration, the water was allowed to stand for a day in order that any cysts present might settle at the bottom of the bottles. The sediment was then collected and centrifuged and examined for cysts. Before filtration the number of cysts present in the settled water varied from 189,000 to 416,000 per gallon. It was found that all cysts of *Endamoeba histolytica* were removed from the water by this treatment. In only one experiment was there the least exception made and in that case the samples of water had stood several days before being tested. No cysts were present in this sample after filtration, but there were a few free living flagellated organisms. As this sample of water was not sterilized, the investigators say it is probable that the organism developed in the filtered water following the passing of the filters by a few organisms. Experiments were conducted to determine also the amount of chlorine necessary in water to kill *Endamoeba histolytica*. It was found that the amount necessary is much more than could be used in a public water supply. This fact in substance had been brought out previously by Craig. Such studies as those here reported on the possible transmission of *Endamoeba histolytica* in water supplies are of the utmost significance. This parasite has become widely distributed in the United States. The information gained should be applied to keep public water supplies free from it.

### MECHANICALLY DISRUPTED BACTERIAL VACCINES

Bacterial endotoxins, according to an old generalization, are incapable of stimulating the production of specific antisera<sup>1</sup>. This generalization would seem however, to be merely a convenient metaphor to express the intracellular location of these specific colloids. Freed from their isolation they are apparently strongly antigenic. Miller,<sup>2</sup> at the University of California, for example, has prepared several extracts or mechanically disrupted pertussis vaccines, capable of producing high titer antiendotoxins in from two to four days after a single subcutaneous injection in rabbits. This prompt antibody response suggests the feasibility of prophylactic immunization after known exposure to whooping cough or of hastening convalescence after the develop

ment of catarrhal symptoms With ordinary pertussis vaccines, Miller could not detect specific complement deviating antibodies in the rabbit circulation until about the sixth to the sixteenth day after vaccination The maximum titer was not reached until the fourteenth to the twenty-fourth day Parallel vaccinations with aqueous extracts or mechanically disrupted bacterial cells, however, led in many cases to demonstrable antibodies by the end of two days, with a maximum antibody titer by the sixth day The sixth day titer was usually from two to four times greater than the maximum after vaccination with intact bacteria Filtration of an extract or mechanically disrupted pertussis vaccine through a Berkefeld filter completely removed its effective endotoxin

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION PUBLIC HEALTH ETC)

### CALIFORNIA

**Society News**—Karl F Meyer, PhD, of the Hooper Foundation, University of California Medical School, San Francisco, discussed infantile paralysis before the Sonoma County Medical Society, June 29, he also spoke on the same subject before a joint meeting of the Solano and Napa County medical societies in Napa July 10—Dr Victor E Stork, Los Angeles was recently elected president of the Southwestern Pediatric Society

**Chiroprapist Guilty of Illegal Practice**—L R Mogle a chiroprapist of Los Angeles was committed to the city jail following a hearing, May 29, when the state board of medical examiners presented evidence of his violation of the state medical practice act Mogle was sentenced to 180 days in jail but was placed on probation for two years on condition that he serve ninety days in jail According to the state board, Mogle has been a 'persistent violator of the state medical practice act in relation to chiroprapy' Evidence showed that he had been giving treatments for various diseases, consisting of massage over the entire body adjusting the vertebrae and cracking the neck He claimed to treat the entire body by prayer or instruction It was also pointed out that he had been attending the American School of Chiropractic, receiving his tuition free in return for his services of instruction on the feet

### COLORADO

**Dr Sewall Honored**—Dr Henry Sewall, emeritus professor of medicine University of Colorado School of Medicine, Denver, was honored June 6 when the Delta chapter of Delta Omega presented to the University of Michigan a bronze plaque in recognition of his early work on antitoxin Dr Sewall conducted his experiments at the University of Michigan from 1882 until 1887 during this time he was professor of physiology at the school a position he held until 1889 In 1887

Dr Sewall published a treatise on his work in immunizing animals against snake venom According to *Science*, the society plans to publish a pamphlet containing a photostatic copy of the original treatise

### DISTRICT OF COLUMBIA

**Report on Tuberculosis Survey**—Recommendations to improve the tuberculosis situation in the District of Columbia have been made to the board of commissioners by a committee appointed to study the adequacy of tuberculosis facilities Members of this committee, appointed by the board following its receipt of a report from the Medical Society of the District of Columbia, are Drs William C Fowler, William Charles White, Prentiss Willson, Joseph W Peabody, Henry J Crosson and F C Smith The committee urges that all tuberculosis activities be centered in a full time tuberculosis officer in the health department, this officer to be supplemented by an advisory board of representatives of tuberculosis agencies in Washington Since there are about 600 deaths from tuberculosis annually in the district, the erection of a 500 bed sanatorium for adults would, in the committee's opinion, increase present facilities and permit the eventual abandonment of the present tuberculosis sanatorium on Upshur Street In addition, the provision of an adequate free tuberculosis clinic is recommended, to receive patients, both white and colored, and of any age at any working hour of every week day The committee recognizes that the tuberculosis conditions in the district are acute and recommends that the commissioners take steps to secure adequate funds from Congress to provide for these emergency measures for the remainder of the current and the coming fiscal year Dr Fowler submitted a minority report, in which he pointed out that a full time tuberculosis health officer would tend to subordinate the position of health officer of the district in matters relating to tuberculosis He urged the creation of the position, however, provided the incumbent serve under the direction and with the approval of the health officer He also feels that the present management of the tuberculosis clinic on its schedule of alternate days has been satisfactory, and that the application of the majority report recommendation would lead to criticism and other difficulties In 1933 the death rate from tuberculosis in the District was 123.8 per hundred thousand population as compared with 122.1 in 1932, it is reported

### GEORGIA

**Personal**—Dr Rufus F Payne, McCaysville, has been named health commissioner for Walker County, succeeding Dr Oscar B Murray, resigned—Dr William L Mathews, Winder, was chosen president of the Alumni Association of Emory University School of Medicine June 9

**Society News**—Speakers before the Sixth District Medical Society at Louisville, June 27, included Drs Charles Hall Farmer Macon on 'Diet and Mineral Metabolism in Children' and William W Chrisman, Macon, 'Collapse Therapy in Chronic Pulmonary Disease'—Dr James Harris Dew, Atlanta, read a paper on 'Posterior Vaginal Hernia' before the Fulton County Medical Society, Atlanta, July 19

**University Sponsors Lectures**—A series of lectures was given in Carrollton, July 9-13, by members of the faculty of Emory University School of Medicine Atlanta, under the auspices of the extension department of the university and supervised by the state board of health The lecturers were

Dr William H Kiser Jr Behavior Problems of Children  
Dr Floyd W McRae Diseases of the Thyroid Gland  
Dr Henry C Sauls Blood Dyscrasias  
Dr Lonnie W Grove Diseases of the Colon  
Dr Cyrus W Strickler Diseases of the Chest  
Dr John F Denton Cancer of the Uterus  
Dr James E Paulin Arthritis  
Dr Montague L Boyd Treatment of Urinary Obstruction  
Dr Edgar D Shanks Cardiovascular Renal Diseases  
Dr Frederick G Hodgson Treatment of Fractures

### ILLINOIS

**Malnutrition Survey**—There is no evidence of unusual malnutrition among school children in Scott County, while the children in Franklin County are better provided for now than in any recent years according to the Illinois State Department of Health which recently completed a five weeks study of child health conditions in the two counties The purpose of the survey was to determine whether malnutrition and other conditions attributable to undernourishment or lack of food have increased among Illinois children during the last four years A total of 2,394 children nearly one half of whom were in the first four school grades in the two counties, were examined These counties were selected as typical of rural and mining counties The physicians making the survey were

of the opinion that there was no evidence of an unfavorable trend that may be charged against economic conditions of recent years

### Chicago

**Study of Hospitals in Russia**—Dr William H Walsh, hospital consultant, sailed, July 21, for London where he will board a soviet steamer for Leningrad. Dr Walsh is making an independent study of health and hospital conditions and practices in soviet Russia and his itinerary will include Leningrad, Moscow, Kharkov, Odessa, Kiev and Minsk. He will return in September via Warsaw, Berlin and Paris. Films on obstetrics made by Dr Joseph B DeLee will be exhibited by Dr Walsh in various medical schools in the soviet union.

**Dr LeCount Receives Award**—Dr Edwin R LeCount, professor of pathology, Rush Medical College has received the 1934 James E Stacy Award by the University of Cincinnati College of Medicine for "his experimental studies on the isolation of streptococci from sore throats and the experimental induction, through their injection, of acute, healing and scarring types of nephritis, identical with the chronic nephritides observed in man." The award consists of a medal and a sum of money and is bestowed for "significant contribution to the theory of focal infection in theory or practice."

**Physical Examination of Relief Employees**—The Illinois Emergency Relief Commission has directed that physical examinations be made of all men and women now enlisted under the Work Relief Administration and those to be employed in the future, to protect the workers from avoidable injury or disease, and the government or other employing bodies from future unjustifiable claims for compensation. The work has been arranged in Cook County so as to give assistance to physicians who are in financial need. Physicians desiring this work should communicate with the Medical Relief Service, 1319 South Michigan Avenue. Groups will be assembled for examination at 1222 South Michigan Avenue. Physicians will be assigned to make examinations during three hour periods for ten consecutive working days not including Saturdays and Sundays, when the unit will be closed. Assignment will be made once each month and reimbursement per month will therefore be \$75 for thirty hours' work.

### IOWA

**Keokuk Alumni Reunion**—Dr Joseph M Trigg, St Louis, was reelected president of the alumni association at the reunion of Keokuk Medical College and the College of Physicians and Surgeons, June 18. Dr Carl S Bishop, Fairfield, was named vice president, and Dr Bruce L Gilfillan reelected secretary. The next reunion will be held in 1936.

**District Conference**—The summer meeting of the Upper Des Moines Medical Society at the Inn on Lake Okoboji, June 28, was devoted to the third district conference, under the presidency of Dr James B Knipe, Armstrong. Speakers included

- Dr Harold C Haben Rochester Minn How Emotions Affect the Body
- Dr Jacob Arnold Bergen Rochester, Diagnosis and Treatment of Various Types of Colitis
- Dr Francis R Holbrook Des Moines Coronary Disease
- Dr Nathaniel G Alcock Iowa City Transurethral Prostatic Resection

Dr Lee R. Woodward, Mason City, was toastmaster at the dinner in the evening, and Dr Gordon F Harkness, Davenport, president of the Iowa State Medical Society, the speaker.

### MICHIGAN

**Typhoid Outbreak in a Circus**—Seventy-seven members of the Ringling Brothers and Barnum and Bailey combined circus were in Detroit hospitals, July 26, half of them ill with typhoid and the others suspected of having the disease, according to the *Chicago Tribune*. Two members of the circus are in a hospital in Cincinnati where the disease apparently first broke out. One person died of the disease a few days later at Dayton. It was first discovered in Detroit Saturday, July 21, when four performers became ill and were taken to a hospital. Circus officials informed the Detroit health department, it was stated, that they believed the disease was contracted in New Castle, Pa, where the show performed, July 13. From New Castle it went to Erie Pa, thence to Cleveland, Columbus, Cincinnati, Dayton, Toledo and Detroit.

**Personal**—Dr William J O'Reilly Saginaw, observed his seventieth birthday, July 3. Members of the staff of St Mary's Hospital attended a dinner in his honor. Dr O'Reilly has been a member of the staff for thirty-nine years and its chief for twenty-four. The completion of fifty years in the practice of medicine by Dr E Herbert Bailey Corunna was

observed by the Shiawassee County Medical Society at a luncheon meeting, June 21.—Dr Harry B Knapp, Battle Creek, has been appointed medical director of the Pocono Nutrition Center at Mount Pocono, Pa.—Dr Theodore R Meyer, Sag Harbor, Long Island, N Y, was recently appointed director of the newly organized health unit of Van Buren County of the W K Kellogg Foundation. Headquarters of the unit are in Paw Paw.—Dr John E Ames was recently elected mayor of Niles.—Dr Kenneth B Moore has been appointed health officer of Flint, succeeding Dr Charles J Scavarda, resigned. Dr Scavarda will continue in the department on a part time basis, however.—Dr Franz Blumenthal formerly extraordinary professor of dermatology and syphilology, Friedrich-Wilhelms Universität, Berlin, has been appointed research professor of dermatology and syphilology at the University of Michigan Medical School for two years, according to Science.

### MINNESOTA

**Personal**—Dr Myron M Weaver, associate professor of health and physical education for men and physician in the college health service, Carleton College, Northfield, has resigned to accept a position in the medical service department of Eli Lilly and Company, Indianapolis.—Dr Archibald H Logan Rochester, received the honorary degree of doctor of science at the annual commencement of Washington and Jefferson College.

**Judge Dissolves Incorporated Clinic**—The Northwest Hair Clinic, Inc, was dissolved through an order of Judge Arthur W Selover in the district court for Hennepin County, June 4. A petition for voluntary dissolution had been filed following an investigation by the state board of medical examiners. The organization had been incorporated in 1932 for the purpose of owning and operating "beauty shops and hair and skin clinics" but had advertised extensively that its work was done under "strict medical supervision." The corporate practice of medicine is not permitted in Minnesota. Neither are lay persons permitted to practice medicine through the medium of employing a licensed physician. Dr C W Wall, Minneapolis, who holds a license to practice medicine in Minnesota and who was a substantial stockholder in the corporation, was the medical director and conducted the actual business for the organization. A certified copy of the order was filed with the secretary of state, which terminates the corporate existence of the firm.

### MISSOURI

**Society News**—The St Louis County Medical Society devoted its meeting, July 25, to a showing of motion pictures on pediatrics.—Dr Paul J Zentay was elected president of the Missouri Social Hygiene Association at a meeting in St. Louis, June 17, succeeding Dr Llewellyn Sale, both are of St. Louis.

**Health at Kansas City**—Telegraphic reports to the U S Department of Commerce from eighty-six cities with a total population of 37 million, for the week ended July 21, indicate that the highest mortality rate (21.5) appears for Kansas City, and for the group of cities as a whole, 10.2. The mortality rate for Kansas City for the corresponding period last year was 9.1, and for the group of cities, 9.5. The annual rate for eighty-six cities for the twenty-nine weeks of 1934 was 11.9 as compared with a rate of 11.3 for the corresponding period of the previous year. Caution should be used in the interpretation of these weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

### NEW JERSEY

**Personal**—Dr Theobald Smith, Princeton, received the honorary degree of doctor of laws from the University of Edinburgh, June 28.—Dr Sidney H Joffe, New York, has been appointed resident surgeon of the Jersey City Medical Center, Jersey City.

**Milk-Borne Epidemic of Septic Sore Throat**—An outbreak of septic sore throat involving 131 cases within a month is described in a recent issue of *Public Health News*, organ of the state board of health. Investigation by the board revealed that most of the cases occurred among users of milk from one dairy. Three cases occurred in the household of this dairyman, the first in a young man who took part in the work of the dairy. His case was followed by the explosive outbreak. The dairy was well equipped and modern and the dairyman was accustomed to have himself and his workers

examined by physicians twice each year, but he did not pasteurize the milk. His herd was tuberculin tested. The investigation showed that six cows were diseased. These were immediately removed and a pasteurizing machine was installed. Because of the fact that the epidemic was not reported until it was in its last stages, satisfactory cultures from the throats of the victims could not be obtained. In a few cultures submitted to a private laboratory it was reported that hemolytic streptococci were found. It is believed that the epidemic was true septic sore throat, however, as the clinical picture of the disease was typical and typical complications occurred. Two deaths occurred in men 55 and 81 years old. The investigator reported excellent cooperation on the part of the dairyman, the citizens, the medical profession, health officers and the local newspaper.

### NEW YORK

**Annual Meeting at Lake Keuka**—The Lake Keuka Medical and Surgical Association held its thirty-fifth annual session at the lake near Penn Yan, July 12-13. Dr Thomas W. Maloney, Geneva, was elected president, succeeding Dr Clare N. Shumway, Painted Post, and Dr John A. Hatch, Penn Yan, was reelected secretary for his nineteenth year. The program included a symposium on cancer presented by Drs. Burton T. Simpson and Louis C. Kress, Buffalo, John J. Morton Jr. and Samuel J. Stabins, Rochester, and Richard B. Cattell, Boston. Other speakers were Drs. Russell L. Cecil, New York, on "Etiology of Chronic Arthritis and Its Bearing on Treatment", William V. Garretson, New York, "Allergy—A Neuro-Endocrine Interpretation", Frederick C. Herrick, Cleveland, "Acute Appendicitis with Peritonitis", William D. Stroud, Philadelphia, "Coronary Disease and Angina Pectoris", and Joseph F. McCarthy, New York, "Medical and Surgical Treatment of the Prostate."

### New York City

**Appointments at New York Polyclinic**—Dr. Joseph Eastman Sheehan has been appointed professor of plastic and reparative surgery at the New York Polyclinic Medical School and Hospital, where a department has been organized for graduate teaching in this subject. Dr. Sidney V. Haas has been appointed professor of pediatrics, and Dr. James P. Croce clinical professor of internal medicine.

**Hospital News**—A grant of \$1,000 has been made by the Simon Baruch Foundation for Medical Research to the Pathologic Laboratories of St. John's Hospital Brooklyn, to carry forward an investigation of fetal endocrine tissue extracts on cell growth. An allotment of \$350,000 from the Public Works Administration will make possible early completion of the new building of the Jewish Memorial Hospital. The new building is eight stories high and will contain 209 beds, in comparison with 117 in the old building.

**A Case of Anthrax**—Thirty-two attaches of Morrisania Hospital recently received antianthrax serum after they were exposed to a case of anthrax in a patient who had been employed in a brush factory. The patient died the day after he was admitted to the hospital. The health department announced that an investigation would be made of the factory to determine if possible the source of the infection. Morrisania was said to be one of four hospitals in the city that receive anthrax cases. Twenty-seven of the attendants who were immunized suffered from serum sickness.

**Interns in New York Organize**—Interns of several hospitals have formed the Intern Council of Greater New York for educational advancement and economic welfare of its members. The council is cooperating with the committee on internships and residencies of the New York Academy of Medicine in investigating the educational aspect of the internship and is also interested in compensation, insurance, maintenance and other intern problems. Dr. Earle H. Harris, Gouverneur Hospital, was elected president and Dr. Arnold Treitman, corresponding secretary for six months, at a meeting June 20.

**Program to Reduce Maternal Mortality**—A program to reduce maternal mortality has been set in motion by the Kings County Medical Society, Brooklyn, through a special committee. Detailed recommendations for an educational program to reach the public, the medical profession, hospitals and midwives were presented in the committee's report at a recent meeting of the society and action to make them effective was authorized. Through various publicity mediums it is planned to encourage prospective mothers to seek prenatal observation by competent physicians to instruct physicians in practical obstetrics

through special lectures and courses, to stimulate better obstetric care in hospitals, especially by the granting of obstetric privileges to all physicians who will agree to abide by the regulations of the institutions, to supervise existing midwives and to cease licensing of such women. Dr. Charles A. Gordon is chairman of the committee on maternal welfare, and members are Drs. Francis B. Doyle, Cameron Duncan, Charles T. Graham-Rogers, William S. Hubbard, O. Paul Humpstone, William A. Jewett, Abraham Koplowitz, Harvey B. Matthews, Vincent P. Mazzola, William C. Meagher, Joshua Ronsheim and W. Sidney Smith.

**Care of the Chronically Ill**—A committee on chronic illness appointed several months ago by the Welfare Council of New York recently made its recommendations to Dr. Sigismund S. Goldwater, commissioner of hospitals. The committee urged that the city administration adopt a definite policy in regard to treatment and care of the chronic sick, that a comprehensive plan for care of chronic patients, based on the medical and nursing service required either in an institution or at home and built around a nucleus of social service, be worked out, that home care and boarding home care be worked out as soon as legally possible, that the unfit buildings of the Neurological Hospital and Cancer Institute on Welfare Island be replaced, and that custodial care under medical supervision be provided for the chronic sick of the city home. A modern hospital for chronic diseases with 500 beds for active hospital cases and with a custodial department for patients in whom disease process is arrested but who have been left with a permanent physical disability was specifically recommended. The committee also asked the commissioner to consider similar development of medical and custodial facilities in Brooklyn. Dr. Ernst P. Boas was chairman of the committee.

**"Psychoanalyst" Convicted of Illegal Practice**—Mrs. May Benzenberg Mayer, alleged psychoanalyst and founder of an institution known as Pojodag House, 112 East Seventy-Sixth Street, was convicted May 29 of practicing medicine without a license. She was sentenced, June 19, to spend a year in jail and pay a fine of \$500. The prison sentence was suspended and the defense announced that the case would be appealed. This is believed to be the first case in which a so-called psychoanalyst has been convicted of illegal practice. Mrs. Mayer was charged with practicing medicine without a license as a result of testimony offered by a woman who had been crippled by infantile paralysis. The woman testified in court that she had paid Mrs. Mayer \$3,185.65 for pamphlets, lectures and treatment. The witness declared that Mrs. Mayer promised to cure her crippled state in five years by psychoanalytic treatments. In addition, the crippled woman was led to lend \$5,300 to meet a mortgage on Pojodag House, of which she received back \$2,800. Mrs. Mayer denied that she was a psychoanalyst. "My work is an important metaphysical experiment which has to do with the study of the subconscious," she said. "When it is completed and a report made, the results will prove very interesting to the public." She had never attended high school or college, it was said, and had been engaged in her present activities for fifteen years.

### OKLAHOMA

**Society News**—Drs. Bert F. Keltz and Harry Wilkins, Oklahoma City, addressed the Caddo County Medical Society, Anadarko, on diabetes and brain tumor, respectively. Speakers at the quarterly meeting of the Southern Oklahoma Medical Association, Chickasha, June 5, included Drs. Ben H. Nicholson, Oklahoma City, on "Uses of Vaccines and Sera in Children", William F. Dean, Ada, "Degenerative Heart Disease of Middle Life", and Charles A. Brake, Norman, "Mental Conditions Associated with Thyroid Dysfunction". At a meeting of the Southeastern Oklahoma Medical Association at Tahlequah, June 26, speakers included Drs. William D. Rosborough, Tahlequah, on "Heliotherapy and Pulmonary Tuberculosis", Louis C. Kuyrkendall, McAlester, "Tuberculosis of the Throat: Diagnosis and Treatment", and Richard B. Ford, Holdenville, "Surgery of the Gallbladder". Among speakers at the midsummer meeting of the Muskogee Academy of Medicine, July 12, were Drs. Edward H. Cary, Dallas, Texas, on "Ocular Manifestations of Nasal Origin", Arthur E. Hertler, Halstead, Kan., "Office Treatment of Stomach Trouble", and Cyrus E. Burford, St. Louis, "Bladder Neck Obstruction". Drs. Harry Wilkins and William W. Rucks, Oklahoma City, addressed the Garfield County Medical Society, Enid, on "Intracranial Injuries" and "Spinal Cord Lesions", respectively. Dr. Powell L. Hays, Vinita, addressed the Woodward County Medical Society, Supply, June 12, on "Sequelae of Encephalitis Lethargica".

## PENNSYLVANIA

**Society News**—The annual meeting of the Seventh Council District of the Medical Society of the State of Pennsylvania was held in Williamsburg, July 11. Drs. Donald Guthrie, Sayre, president, Moses Behrend, president-elect, and Walter F. Donaldson, secretary, of the state medical society, made short talks on organization activities and Dr. Harold A. Miller, Pittsburgh, state director of emergency medical relief, discussed relief plans. Drs. Emil Novak, Baltimore, and Harvey F. Smith, Harrisburg, spoke on functional gynecologic problems and appendicitis, respectively.—The Chester County Medical Society has arranged a campaign to reduce appendicitis mortality to be held during October and November, addresses will be made by members in seventeen communities in the county.—Dr. Joseph W. Fisher, Pittsburgh, was elected president of the Pennsylvania Radiological Society at the annual meeting at Pocono Manor in May.—At a meeting of the Northwestern Pennsylvania Medical Society at Oil City, June 27, speakers were Drs. Dean Lewis and John T. King Jr., Baltimore on "Fractures and Their Complications" and "Causes of High Blood Pressure," respectively, and William V. Mullin, Cleveland, "Hoarseness Its Differential Diagnosis".—Dr. Hugh Cabot, Rochester, Minn., addressed the fifty-fourth annual meeting of the Lehigh Valley Medical Society, Allentown, July 19, on "Development of Prostatectomy, with an Appraisal of Present Methods."

## TEXAS

**Society News**—Dr. Cleve C. Nash, Dallas, among others, addressed the Dallas County Medical Society, June 14, on "Chronic Subdural Hematoma", the society heard Dr. Kelly L. Cox, Dallas, June 28, among others, discuss "What the General Practitioner Should Know About Glaucoma".—The North Texas Medical Association met in Terrell, June 5-6, with the following speakers, among others: Drs. Tate Miller, Dallas, "Modern Aspects of Amebic Infection"; Joseph D. Becton, Greenville, "Suppurative Peritonitis"; Preston W. Pearson, Emory, "Dietetics in Pregnancy"; and Richard L. Nelson, Dallas, "Lead Poisoning in Children with Special Reference to Encephalitis".—Drs. George D. Mahon Jr. and Ben R. Buford, Dallas, addressed the Wichita County Medical Society, Wichita Falls, May 8, on "Toxic Thyroid" and "Treatment and Diagnosis of Common Heart Conditions," respectively.—Drs. R. A. Roberts, San Antonio, and Percy C. Anders, Lockney, addressed the Hale Swisher-Floyd-Briscoe Counties Medical Society, Plainview, May 8, on vitamins and eclampsia, respectively.—Dr. Quincy B. Lee, Wichita Falls, addressed the Baylor-Knox-Haskell Counties Medical Society, Goree, June 12, on "Unusual Manifestations of Appendicitis."

## UTAH

**Personal**—Dr. Charles Griffin Plummer, Salt Lake City, received the merit award of Northwestern University Alumni Association on "illumination night" in Evanston, Ill., preceding the annual commencement exercises, June 15. The award is a certificate given annually to alumni for "worthy achievement which has reflected credit upon their alma mater."

## VIRGINIA

**Graduate Courses in Obstetrics Ended**—The tenth circuit of the graduate course in prenatal and postnatal care which has been sponsored during the past two years by the Medical Society of Virginia, the Medical College of Virginia and the University of Virginia ended the series for the present. Dr. Maxwell E. Lapham, Philadelphia, has been field clinician. Every medical society in the state with enough members to form a class has been offered Dr. Lapham's services and practically all have been served in the program. The tenth circuit, which began July 9 and will continue ten weeks, includes the towns of Alexandria, Fairfax, Fredericksburg, Culpeper and Orange. The preceding courses had enrolled 594 physicians in fifty classes. Funds for this intensive program have been supplied by appropriations amounting to \$6,000 by the state medical society and grants from the Commonwealth Fund amounting to \$15,000. The enrolment fee was \$5.

## WISCONSIN

**Personal**—Dr. Hjalmar T. Kristjanson, Milwaukee, was reelected president of the Associated Diplomates of the National Board of Medical Examiners at the annual meeting in Cleveland.

**Society News**—Speakers at the meeting of the Fifth District Medical Society, Sheboygan, May 31, were Drs. John W. Harris Madison, on prenatal care, Henry W. Meyerding, Rochester, Minn., fractures, Frank Smithies, Chicago, amebic dysentery, and Edwin G. Bannick, Rochester, acute abdominal conditions.—Drs. Richard S. Rogers, Junction City, Ore.

Francis T. McHugh, Chippewa Falls, and Clifton A. Cooper, Colfax, presented a symposium on obstetrics at the June meeting of the Chippewa County Medical Society in Chippewa Falls.

## GENERAL

**Bequests and Donations**—The following bequests and donations have recently been announced:

United Hospital Port Chester N. Y. \$5,000 by the will of the late Julia Trendwell.  
St. John's Hospital Brooklyn \$15,000 and the floating hospital of St. John's Guild \$1,000 by the will of the late Mrs. Josephine Erwin.  
Mount Sinai Hospital New York \$1,981 by the will of Emil Kiss.  
Brooklyn Hospital and Wyckoff Heights Hospital New York \$5,000 each by the will of the late John W. Weber and Eastern Long Island Hospital \$1,000.  
Staten Island Hospital \$1,000 by the will of the late John White.  
New Rochelle Hospital \$5,000 by the will of the late James R. Merrill.  
Hospital for Relief of Incurable Cancer Hawthorne N. Y. \$40,000 under the will of the late Bertha M. Coughlan \$10,000 and the residual estate under the will of Eliza J. Kraiz.  
Bellevue Hospital New York children's division will receive most of the estate of the late Mrs. Anna Phipps Tinker estimated at \$300,000 in memory of her husband the late Dr. Horace H. Tinker. Half is bequeathed outright and the remainder is contingent on the death of beneficiaries.  
Brooklyn Hospital Brooklyn \$5,000 by the will of Sarah T. Bailey.  
Lankenau Hospital, Philadelphia is to be ultimate beneficiary of the \$30,000 estate of William F. C. Griepenkert Oak Lane according to his will probated June 28.  
Memorial Hospital, Norwalk Ohio \$7,000 and the International Society for Crippled Children Elyria Ohio \$9,000 by the will of the late Mrs. F. M. Kirk.  
Methodist Episcopal Hospital Brooklyn \$20,000 by the will of the late Mrs. Katherine Mead Sloan.  
Delaware County Hospital Drexel Hill Pa. \$5,000 by the will of Mrs. Louise Mende Hembold.

**The Lowest Birth Rate**—There were 2,064,944 births in continental United States in 1933, giving a rate of 164 per thousand of population, the lowest on record since the federal birth registration area was established in 1915, when it included only ten states and the District of Columbia, according to provisional statistics issued by the Bureau of the Census. This figure compares with a rate of 174 for 1932 for the birth registration area, which at that time did not include Texas. In 1933 the infant mortality rate was 58.2 per thousand live births as compared with 57.6 in 1932. New York with 187,139 births led the states with the greatest number of births, Pennsylvania was second with 157,046, Texas is third with 107,924 and Illinois, 106,861. The states with the highest birth rates per thousand of population, however, are New Mexico, 267, North Carolina and Utah, each 229. South Carolina, 227, Mississippi, 216, Alabama, 211, and Virginia, 21. All except Utah are southern states and all largely rural. The lowest birth rates are for Oregon, 12.2, and California, 12.4. Infant mortality rates, which are based on the number of deaths of infants under 1 year of age per thousand live births, are excessively high in New Mexico (134.2), and Arizona (111.4), both states with large nomadic Indian and Mexican populations which have little knowledge of infant care. The next highest rate is 78.4 for South Carolina, which has a large Negro population. The lowest rates reported are those for Washington and Oregon, 38.9 and 39.3, respectively. A rate of 37 per hundred live births was noted for stillbirths.

**Impostor Jailed**—An impostor with many aliases who has been traveling about the country for years victimizing physicians, was recently arrested in Boston after he was recognized by a physician from Atlanta who knew of his activities there. Wilder the name used in this instance, had approached physicians at the Peter Bent Brigham and Children's hospitals Boston calling himself a pathologist from Singapore and requesting the courtesy of visiting laboratories. The Atlanta physician recognized Wilder as 'Dr. John Bellinger,' who used the same tactics in Atlanta and who left a trail of worthless checks behind him. Wilder confessed when he was identified by this physician and was placed in the city jail. Various names by which he has been known include Ernest Donald Roberts, Dr. A. L. (Jerry) Castle, Dr. Gwyn Chadwick, Dr. John Bellinger and Dr. George Neville. The impostor's method of approach is nearly always the same. He calls on physicians and, with his pleasing manner and medical knowledge, manages to win their confidence. After becoming acquainted he usually entertains generously and on his departure it is found that he has cashed numerous worthless checks. He is well informed on medicine and prominent physicians, well versed in English, French, German and Greek, and is conversant with music and literature. He also plays polo. He has pursued his activities in many places including Atlanta, Albuquerque, N. M., San Francisco, Santa Barbara, Palo Alto, Calif., Seattle, Wash., St. Louis and Kansas City, Mo., Lincoln, Neb., Dallas, Texas, Nashville, Tenn., Madison, Wis., and Duluth, Minn. (THE JOURNAL, April 15 1933 p. 1196).

#### Financing Hospitals by Sweepstakes

The total amount subscribed to the last Irish Hospitals Sweepstake amounts to nearly \$15,000,000. Of this about \$9,000,000 was expended in prizes and the hospitals received \$2,600,000, the remainder being government taxation and promoters remuneration. To date about \$150,000,000 has been received for these sweepstakes, mainly from other countries than Ireland and about \$100,000,000 has been distributed in prizes. Great Britain has subscribed about two thirds of the money and also received two thirds of the prizes. Ireland's subscription amounts to only about 7 per cent of the total. The Irish hospitals have received in all about \$32,500,000. At first, aid was given only to the Irish voluntary hospitals, but the government now allots a portion of the proceeds to tax-supported hospitals. So great has been the amount received that it is now proposed to endow the hospitals, so that support will be forthcoming even if this novel source of income should dry up. It is also proposed to finance research work in Ireland by these sweepstakes.

This method of financing hospitals by taking advantage of the gambling spirit of the world has been highly successful in Ireland, but such a method is not approved of in Great Britain. The prevention of this drain has become a problem for the British government. These sweepstakes are illegal here, but the attempt to prevent subscription to them has not been successful. A few prosecutions of persons selling tickets have taken place, but the effect has been negligible. The government is now attempting by new legislation to deal with the evil. It has introduced a betting and lotteries bill in order to deal more effectively with such large sweepstakes. It prohibits absolutely the publication of lists of prize winners. At present these are such an important news item that when the lists are published the placards of the evening papers are given up to them. The bill also prohibits the publication of any other matter relating to the sweepstakes calculated to induce persons to participate in them. It is made an offense to bring into this country any tickets or advertisements for the purpose of sale or distribution. The bill prohibits the sending abroad by agents in this country of counterfoils or money derived from the sale of lottery tickets. All such money will be forfeited. These provisions have been welcomed by nearly every section of the press.

As to aid for English hospitals by such means the hospital authorities do not desire to enter on such speculation as they are receiving contributions from every working man throughout the country in addition to the subscriptions of charitable persons. The government has therefore decided against legalizing large-scale lotteries for the support of hospitals although this has been demanded by some influential persons. On the other hand the important puritanical and nonconformist section of the English people is opposed to such lotteries on moral grounds.

#### International Conference on Vitamin Standardization

The second international conference on vitamin standardization has been held in London under the chairmanship of Dr Edward Mellinby FRS. All the great countries excepting Germany were represented. Dr Nelson represented the United States. The conference was remarkable for two things. The conclusions were unanimous which can be explained by the fact that all the members were experts and Sir Henry Dale

FRS, of the Permanent Standards Commission, suggested that all having editorial influence with any journal should bring pressure to bear so that all papers on vitamins, in which units other than the international were used, should be refused. The following recommendations for standardization await confirmation by the Permanent Committee on Biological Standardization.

#### VITAMIN A

Pure beta-carotene, of melting point 184 C and optically inactive, is recommended in place of impure carotene, provisionally adopted before. The previous unit was 1 microgram of the standard carotene. Beta carotene is more active and so the corresponding amount is 0.6 microgram. Coconut oil has proved so satisfactory a solvent that distribution of the pure carotene in solution is recommended to avoid the difficulties which workers have with the crystalline material. As a subsidiary standard, a sample of cod liver oil the potency of which in international units has been well established is recommended. A spectrophotometric test measuring the coefficient of absorption at 328 millimicrons in strictly defined circumstances is held to be a satisfactory measurement for vitamin A in liver oils and concentrates.

#### VITAMIN B<sub>1</sub>

The adsorbate on acid clay, previously adopted, has been found most satisfactory and is therefore recommended.

#### VITAMIN C

Like vitamin A, vitamin C can be prepared as a pure substance. The lemon juice previously adopted as a standard is therefore abandoned and *L*-ascorbic acid, as defined by physical constants, takes its place.

#### VITAMIN D

The old standard of viosterol in olive oil has been found quite satisfactory. No advantage was to be gained at present by attempting to substitute for it crystalline vitamin D. There is still a large stock available. Provision was made for such an ultimate change when it should appear desirable. But one trouble has arisen. It has recently been found that animals do not all utilize different antirachitic materials in the same proportions. Thus cod liver oil is much more potent than viosterol when tested on chickens than when tested on rats. Therefore a much larger number of units would be attributed to the oil if chickens were the test animals than if rats were. Possibly similar differences may exist in other animals. To define the animal to be used for the test is considered to be a defect of biologic standardization. Possibly further research will remove this difficulty.

#### OTHER VITAMINS

Pure lactoflavine as a standard for vitamin B<sub>2</sub> was considered but its use was held to be premature. There seemed to be no hurry in the matter, as deficiency of vitamin B<sub>2</sub> is not yet definitely connected with any disease or syndrome in man.

#### Hirsuties in the Female Treated by Ovarian Hormone

At the Section of Dermatology of the Royal Society of Medicine, Dr A. D. K. Peters brought forward a new treatment of hirsuties in the female which depends on recent advances in knowledge of the sexual hormones. A woman aged 38 complained of hirsuties which she had for eighteen years. Her general health was good and menstruation was regular. Though she had married at 25 there were no children. She had a feminine physique but a heavy growth of curl hair on the moustache and beard areas, the inner sides of the thighs and the upper part of the legs. The suprapubic hair was of feminine distribution. The eyebrows were heavy.

but the hair of the scalp was fine. Crystalline trihydroxy-estrin, 100 Doisy rat units (approximately 330 international units) was taken by mouth daily for a week. Nineteen days after the administration was begun the hairs began to fall from the moustache and beard areas. This continued for a while and then gradually decreased until it ceased sixty-two days after the administration. The treatment was repeated and the hair again fell. Bare oval areas about half an inch long were left on the chin. A month later crude keto-hydroxyestrin, 1,000 international units (approximately 303 Doisy rat units), was taken every day by mouth for ten days. Hair fell at the rate of two or three hairs daily. The dose was increased to 2,000 units with the same result. The loss of hair was always greater from the chin than from the upper lip. An earlier but diminished response followed each course of treatment. In the end there was still a moderately heavy moustache but only a few stiff hairs on the chin. However, hair was beginning to grow again. The case appeared to be one of endocrine imbalance. It is proposed to institute more vigorous treatment. Kaufmann has shown that enormous doses of estrin are necessary to obtain full therapeutic results. It is suggested that, if the feminine type could be established, slight dosage might maintain it.

### PARIS

June 10, 1934

#### The Birth Rate of France

The bureau of statistics has published a final report on the vital statistics of France in 1933. The general results are frankly unfavorable. There were 40,000 fewer births than in 1932, 200 more deaths and 600 more marriages. The excess of births over deaths was reduced to 21,600, as compared with 61,400 in 1932. The birth rate was reduced from 17.3 to 16.3 per thousand of population, the mortality remained stationary, and the number of marriages showed but slight variation (15.1, as against 15.0). The reduced birth rate is manifest chiefly in the southern departments of France. The central region shows little variation over the previous year. The excess of births over deaths is found chiefly in the departments of the North, West and East and has been so every year for a considerable period. It is surprising that the warmer regions of the South have fewer births, for Italy, under similar conditions, has an excess of births over deaths. In southern France, however, the population is less inclined to work hard. The people live a great deal in the open air and are fond of discussing, to little purpose, questions of politics, while the interest in religious questions is diminished. In place of industrial or agricultural work, they seek positions in the cities as employees or so called civil servants. In this environment, increases in families appear to be less welcome. On the contrary, in the agricultural regions of Bretagne and Normandy, in which religious sentiments are more manifest and the interest in manual toil is greater, the families are larger. Children work in the fields at an early age. Similar conditions are found in the industrial regions of the North and the East, which are likewise more religious. In these regions school attendance is less rigorously supervised. The mayors of villages who have charge of school matters are inclined to permit peasants to keep their children at home for work in the fields. The conclusion is that the excess of births is in direct relation to the early use of the working power of the child and is in inverse proportion to school attendance, the progress of school instruction and interest in religion. Economic factors appear to be dominant. The number of children is evidently greater

in regions where their services are profitable and is diminished in regions where their presence is a burden on the family budget. The departments that have the most divorces have the smallest number of children per family. Widespread unemployment has caused many foreign workers to return to their own country, particularly the Poles and the Czechoslovakians, who came to France after the war. These foreign peasant families have always been more prolific than the French. The unchanging nature of the birth rate shows no improvement in spite of the development of the prophylactic services, the dispensaries and the hospitals.

#### The Status of the Ministry of Public Health

Considerable discussion is being awakened in medical circles on the subject as to whether parliament acted wisely in creating in 1920 a special ministry of public health. Up to that time the bureau of hygiene was a subdepartment of the ministry of the interior, which controls, from the administrative point of view, the prefects and the various public departments. For years the physicians had been loudly demanding the creation of a special ministry of health, which would be independent in its tasks and in its budget. The ministry was created in 1920 but in 1924 it was abolished and made a subdepartment of the ministry of labor, chiefly for political reasons, the purpose being to connect it with the passage of the baneful law pertaining to social insurance, which was about to be promulgated, the idea being to give the law the appearance of a health measure and thus mask its demagogic purpose. The ministry of public health was reestablished in 1930, but for several years the department was in the hands of politicians not one of whom was a physician. They represented merely a group of the party in power, the members of which the government wished to appease. The choice of the head of the ministerial department, regarded as of a secondary order, was not considered of great importance. The present incumbent, Mr. Louis Marin, who is a lawyer, confessed frankly, in an imprudent interview, that he had never paid special attention to health problems and that he was obliged to rely on the high officials in the various offices.

One of these ministers, Mr. Justin Godart, likewise a lawyer, took his duties seriously. He created a public bureau of social hygiene and established the Parti social de la Santé publique. But he disappeared, along with the others, with the next political upheaval. Recently the decrees resulting from the situation occasioned by the readjustment of the budget again brought the bureau of health under the ministry of the interior. This amounts, to a great extent, to a return to the conditions existing previous to 1920 and may be the prelude to the reabolition of the ministry of public health. Dr. Doisy, who is a deputy from the Ardennes region and who demanded with great energy the creation of this ministry when he was a member of parliament, admits today that this ministry has been the source only of disappointments, chiefly because of the instability of the heads of the department. He thinks it would be better to have a special subdepartment acting under the ministry of the interior and having as its head a professional hygienist uninfluenced by the fluctuations of political parties. A humorous side of the question is the fact that this view was entertained in 1925 by Louis Marin himself, the same man to whom the Doumergue ministry awarded the office of minister of public health, of which circumstance one of the newspapers has reminded him. The important thing is that the departmental directors of hygiene, who are the necessary units of the whole organization, be well chosen and that sufficient authority be accorded them that they can compel the prefects to carry out the administrative measures that they have decided on.

### Industrial Poisonings Due to Benzene

Poisonings from the use of benzene are becoming more numerous as the industrial use of substances with a benzene base becomes more widespread. Dr. Heim de Balzac, director of the technical institute of the Conservatoire des arts et métiers, has reported the results of his investigation of the subject. He expresses regret that great confusion exists in the terms used in various countries to designate the various products employed, without any account being taken of their origin—a distillation of either gasoline or coal tar. The word "benzin" designates in Germany essence of petrol (gasoline) and in France one of the products of the distillation of tar, which the Germans call "benzol", but in France benzol signifies a mixture of hydrocarbons of coal. As these various products are often imported from foreign countries under the names peculiar to the country of origin, it sometimes happens that industrialists are ignorant of the degree of toxicity of the product that they are using. Under different names there are twenty or more different products, none of them alike, employed as solvents in the manufacture of rubber and varnishes. Of all these substances, pure benzene ( $C_6H_6$ ) is the most toxic. It is not used in a pure state but only mixed with toluene and xylene. Heim de Balzac distinguishes therefore, in the French factory, benzénisme, benzolisme and benzénisme. However, it appears that some authors who have written on the subject have confused these facts. Essence of petrol (gasoline) is only weakly toxic in its effect on the nervous system, whereas benzene and the substances associated with it in the distillation of coal are protoplasmic poisons, with predilection for the blood, the hematopoietic and the central nervous system, heat production and the oxidation processes. They exert an action also on the walls of the vessels, which they render fragile and predisposed to hemorrhages. One observes a diminution of the erythrocytes and of the hemoglobin index. Chronic poisoning with benzene is manifested by a more or less marked anemia, with hemorrhagic tendencies and sometimes fatal results. Heim de Balzac cited the case of a shop for the manufacture of varnishes where suddenly a series of poisonings developed affecting 50 per cent of the force and causing eight deaths. Inquiry revealed that the accidents followed the use of a solvent for rubber, with a pure benzene base, which had been substituted for essence of petrol (gasoline) heretofore used. Rejection of the benzene and a return to essence of petrol (gasoline) put an immediate end to the accidents. A fatal case was observed in a small shop of the Paris region with a similar origin, namely, the substitution of benzene for essence of petrol (gasoline). At the present time, benzene is used more and more as a solvent of new sprayed varnishes used on automobile bodies, and accidents are becoming more frequent. Heim de Balzac recommends a thorough inspection of all the industrial establishments in which benzene is employed, extensive aeration and a periodic medical examination of all the workmen, including examination of the blood, blood count and percentage of hemoglobin so as to discover early the blood changes that characterize the onset of the poisoning. An early sign of great value consists in the elicitation of blue spots on the skin by means of light taps on the sternum or the application of a tourniquet to the arm.

### The Congress of French-Speaking Physicians

The Congrès de médecine de langue française, which meets annually and is held alternately at Paris and in some large city of a French-speaking country, will convene this year at Quebec, at the invitation of the Canadian government, which desires to have the congress held in connection with the ceremonies in commemoration of the fourth centenary of the discovery of Canada by the French navigator Jacques Cartier. About 150 French professors and physicians have enrolled and will embark August 18 on the transatlantic steamer *Champlain* chartered for the occasion. All will participate in an excursion

through the United States and will visit during the first week in September Chicago, Rochester (Minn.), Washington and New York, where they will embark, September 9, for the return voyage.

### The Society for Research on the Circulation

The chief topic at this year's session of the Deutsche Gesellschaft für Kreislaufforschung, held under the chairmanship of Professor Norr, veterinarian of Munich, was "Thrombosis and Embolism." The first paper was presented by Aschoff of Freiburg, who discussed remote thrombosis as the most important source of lung embolism. With few exceptions the thrombus is located in the veins of the thigh and pelvis, which points to the static factor in the development of thrombi. The conditions favoring the development of the remote thrombus are retardation of the blood stream, the behavior of the blood platelets as to number and agglutinability, and the behavior of the protein bodies of the blood. Of the external factors that play an important part, mention may be made of changes in the general nutrition. The increase of thrombosis since the war is regarded as due mainly to sharp fluctuations in the diet, particularly the fat intake. Recently the frequency of thrombosis has declined, doubtless because the diet of the population is again better balanced. Also persons affected with obesity or high blood pressure have a tendency to thrombosis and embolism—furthermore, infections, operative interventions, losses of blood, and possibly also changes in the carbon dioxide tension of the blood. A. Dietrich of Tübingen emphasized the significance of injuries of the vessel walls in connection with thrombosis. According to his view the formation of thrombi is based chiefly on changes in the endothelium, the increased precipitation of platelets occurs then secondarily.

On the second day, Morawitz of Leipzig called attention to the fifteenfold increase of thrombosis and embolism during the postwar period, and particularly during the years of inflation. At the same time an increase in circulatory disorders was noted. The relation between the two disorders has not been fully clarified. In Europe, Germany was chiefly affected, and the older more than the younger age groups. No single cause can be brought forward in explanation of thrombosis, the blood and the blood vessels are an anatomic and functional unit—a single organ, a sharp separation, such as was brought out in the first papers, did not appear feasible. Morawitz described the relations between blood platelets and thrombi. The tendency to thrombosis varies in different morbid conditions, depending on the behavior of the blood platelets and the plasma (agglutinins). There is no way to prevent the progress of a thrombosis, therapeutics has not introduced any new methods.

Nurnberger of Halle stated that in gynecologic practice the increase of thrombosis and embolism has not been so widespread. The cause for local increases could not be established. In diagnosis, the pain symptoms in thrombosis of the pelvic veins, especially rectal, abdominal and shoulder pains, are important. One observes also plantar pain and pain in the calf of the leg, a spastic venous strand in the groin, dysuria, anal pain during an enema, and meteorism, likewise increased cutaneous sensitiveness as a sign of 'silent embolism,' which appears about the fifth day after an operation, along with lung and heart symptoms and shoulder pain. As prophylactic measures, numerous methods are used to speed the blood circulation: massage, gymnastics and inhalations of carbon dioxide. Statistics on early and late rising after an operation are conflicting. In septic thrombophlebitis, ligation of the veins seldom affords much benefit.

## Research on Cardiac Infarction

Professor Brugsch of the University of Halle and Dr Misske presented recently the results of their research on cardiac infarcts. Angina pectoris is associated with infarct of the myocardium in a third of all cases, although it is not a leading symptom. The leading symptom, fear of death, affects the whole vegetative nervous system, hence the cold clammy sweat and aspect of collapse. Angina pectoris serves the purpose of a brake. The patient with angina pectoris stops short if he has an attack on the street, then the pains recede. In case of cardiac infarct, the patient is seized with fear, with or without heart pain. After the attack there comes a lowering of blood pressure, amounting sometimes to from 70 to 80 mm. The cases in which the blood pressure falls below 80 mm are desperate. Cardiac infarct is often wrongly diagnosed, necrosis of the pancreas is likely to be thought of because of collapse and the swelling of the abdomen. A leukopenia may be observed in pancreatic necrosis, whereas in cardiac infarct a leukocytosis is present. The electrocardiogram is of great aid in diagnosis. One must distinguish between an intramural and a septum infarct. In intramural infarct the currents in the damaged area produce in the electrocardiogram the monophasic instead of the pluriphasic course of ventricular activity, called upward deflection of the ST portion. In the septum disturbances the changes are characteristic for disorders of the bundle of His. The most frequent form of the infarct is that affecting the descending branch of the left coronary artery. Therapeutically, nothing should be given by vein. One or two days after the attack, a clysis of a digitalis infusion (15-200) may be given in two days in four portions. Digitalis will usually raise the blood pressure about 20 mm. On the fourth or fifth day, an attempt may be made to inject slowly a 20 per cent dextrose solution. After from eight to ten days an intravenous injection of strophanthin is permissible, but not without theophylline ethylenediamine and dextrose. The injection must be made very slowly. It takes from six to eight weeks before the patient recovers to a certain extent. The patient should take a long rest. All clinically diagnosed infarcts are large. Small infarcts cause chronic heart weakness. The pain of angina pectoris may be harmless or it may be the forerunner of an infarct. Most infarcts manifest themselves without the angina pectoris. The diagnosis of coronary thrombosis or of infarct of the myocardium can be made in most cases by the electrocardiogram. The ventricular complex shows characteristic changes affecting particularly the ST interval with abnormal T deflection below the line. In place of the RST segment above the line an ST portion is often found below the zero line. The ST interval with the inverted T ("coronary T") wave may, years later, betray the coronary blocking or the infarct of the myocardium, although, in the course of time, the normal wave form may be reassumed. Occasionally it is possible to determine the location of the heart muscle injury from an inspection of the typical change in the RT segment and to distinguish an anterior from a posterior infarct. From their own observations, Brugsch and Misske were not able to set up a rigid scheme of electrocardiographic changes in blocking of the coronary system. An enlargement of the Q peak in the second and third deflection (Q III larger than Q II), combined with changes in the T peak or of the intermediate portion in the same deflection may be regarded as a sign of an infarct. The same importance attaches to the occurrence of a depressed Q I. Besides the changes in the ST interval and the T peak they found most frequently intraventricular disturbances of conduction in the form of a blocking of a main stem or of a branch, and they always found blocking of the right main stem and never of the left. This is explained in part by the fact that the left

main stem gives out many fan-shaped branches and hence cannot be so easily and completely blocked as can the simple strand-shaped right main stem, which does not usually divide into three branches until it reaches the base of the large papillary muscle. Also the distribution of the blood supply may be responsible. Only in about 8 per cent of the cases is the left ventricle supplied exclusively by the left coronary artery. Hence for a left-sided complete ventricular blocking a closure of both coronary vessels is necessary, whereas the closure of a small septal branch from the ramus descendens is sufficient to block the right stem completely in its lower course.

Mahrum distinguishes an anterior cardiac infarct resulting from a disordered condition of the descending branch of the left coronary artery, and a posterior infarct, which occurs in two forms, the high infarct, in which the atrioventricular node and the common trunk are affected and the depressed infarct with injury of only the left posterior branch. Similar conditions may be observed also in myocarditis diphtherica and narrowing of the coronary orifices in syphilitic aortitis, with defective blood supply in the septum. In association with blocking of the descending branch of the left and the right coronary artery, Brugsch and Misske, in addition to intraventricular conduction disturbances, observed auricular fibrillation with absolute arrhythmia of ventricular activity.

## Composition of the Jewish Population in Vienna, from the Standpoint of Anthropology

At a joint session of the Gesellschaft für Rassenkunde and the Anthropologische Gesellschaft of Austria, over which Prof Dr Wagner Jaueregg presided, discussion arose over the composition of the Jewish race in Vienna. Since scientific research may still be carried on in Austria unhampered by politics, which is an impediment in Germany, the results of such a discussion should be interesting. The discussion was opened by the investigators Dr S Hella Poch and Robert Routil, assistant professors at the Anthropologie Institute of the University of Vienna. The methods of measurement and observation had been worked out in Vienna and had been applied to the Bushmen in South Africa and, during the World War, to Russian African and Asiatic war prisoners. The initial stimulus to the comparative measurements on the 200,000 Jews of Vienna came from the investigation of the geographers Prof H V Wissmann and Prof Dr Rathjaens of Hamburg, who during extensive travels in Arabia, and particularly in Yemen, had collected photographs and measurements of Arabians and Jews and had turned them over to the Vienna Institute, where new material was added. The result of the research was to the effect that at least seven distinct racial types, and possibly three more, are distinguishable in the Jewish people of today. The Jews of Yemen seem to belong to an ancient and primitive racial type, especially in the oases. By taking their racial characteristics as a basis for comparison, a classification of the various groups of the Jewish people becomes possible and serves to correct previous erroneous conceptions. The Jews still show elements of races that long ago left their original place of settlement. Their anthropologic history goes back, then, to two ancient Semitic races: (1) the Canaanites, who still live in Palestine under the name of Samaritans—large and tall individuals with large noses and fairly long heads, and (2) the Accadians, which include the Babylonians and the Syrians of Mesopotamia—of average height, with short heads and sharply curved noses. The original Jews received a part of their foreign blood while still in Palestine, through which foreign peoples were constantly passing and a further part on their

own wanderings, which have extended over the whole world. The present day types can be shown to possess characteristics of the Hittites and Ammonites, also qualities of the populations of southern and southeastern Europe (Greeks, Scythians, Syrians), which may be given special mention as parts of the oriental parent stock. Various marks and characters that were noted in skulls and sculptures 5,000 years ago may be observed today precisely as they were centuries ago and thus prove the connection between ancient and modern times. It is evident that in the ancient types there were *daerotypen*, or persistent types. For thousands of years no fundamental changes in the races of man have occurred, the modification that has developed being due solely to crossings, which can be demonstrated by anthropologic methods. The racial mixture constituted by the Jews of Vienna shows thus characters of oriental peoples who came down from the North mingled with racial characteristics of North African Berbers, Abyssinian Negroes, Old Egyptians, Fellahs and various European peoples. During the discussion, which was comprehensive, Professor Oberhummer stressed the aspects of primitiveness that cling to the Jews of Yemen. Professor Christian pointed out that the Canaanites had mixed with the Jews, or Hebrews. The Amorites, who likewise were in Palestine before the Jews, are of North European origin. They intermarried soon with the new lords of the land, and traces of their racial stock are distinctly observable in the Jews of today. Dr. Frankfurter called attention to the widespread mingling of peoples in Europe, whereby the races of man were changed and the somatic characteristics of the Jews were so markedly influenced.

#### Public Lectures on Health by Laymen Prohibited

A recent order of the public health service provides that the presentation of public lectures on therapeutic methods and the functions of the human body and its organs by persons who have not been admitted to the practice of medicine in Austria shall be prohibited because of the associated menace to public health. This order applies to the entire area of the republic of Austria. It does not, however, extend to lectures delivered before private societies or to speakers who although not authorized to practice in Austria are practitioners in a foreign country. Lay practitioners will not be permitted to deliver lectures in Austria even though they are allowed to practice the healing art in some foreign country. Violations of this order will be subject to fine and imprisonment.

#### Protection of Workmen in Certain Industries

About a year ago the public was stirred by the poisoning of seventy-two girls employed in a factory manufacturing rubber goods in which benzene and xylene were used. During the court action that grew out of the disaster the laws bearing on the situation were declared by the public health service to be inadequate. The federal ministry of health then issued a regulation designed to protect the health of employees in manufacturing plants in which the following chemicals are used: benzene, toluene, xylene, trichloroethylene, tetrachlorethane, carbon tetrachloride and/or carbon disulphide. Workmen will not be permitted to work longer than four hours a day in rooms in which they might be exposed to the fumes of such substances. Where carbon disulphide is being used the time is cut to two hours a day. No women or boys under 18 years of age may ordinarily be employed on work with chemical products in which injurious vapors cannot be avoided, as in the manufacture of varnishes or paints, the production of rubber articles, glues and pastes or waterproof substances or printing presses or other presses when such work necessitates the use of benzene, toluene, xylene or carbon disulphide. If however the concentration of poisonous substances is no stronger than 10 per cent they may by exception be allowed to work

provided an effective suction apparatus has been introduced. Persons employed in such plants must report for a health examination at intervals of three months, when the composition of the blood must be carefully ascertained. The costs of the examination must be borne by the employer. If, after two years of regular periodic examinations, the health of the workmen has been found to be good, the interval between examinations may be lengthened. Workmen who are found to be ill or to display insufficient resistance will not be permitted to work again in such plants. Establishments using these dangerous substances will be required to keep a record card for each workman, which will state the nature and duration of the employment, the dates and results of the periodic medical examinations, and, in the case of illness, the nature, course and termination of the illness, and the day on which work was resumed by the examinee.

#### Treatment of Avulsion of the Scalp

Dr. Schnek, of the University Surgical Clinic in Vienna, demonstrated recently before the Gesellschaft der Aerzte a case in which a cure was effected in grave scalp injuries. The patient was a woman worker 20 years of age, who, six weeks before the demonstration, had been caught by the hair of the head in a revolving shaft. The hair was twisted into a roll, and a circular skin flap of the scalp about 6 inches in diameter, beginning with the frontal hair border, was torn loose from the head. Half an hour later the injured woman was at the emergency station of the clinic, in a fairly good condition. The edges of the wound were fairly smooth, except on the forehead. The periosteum of the parietal bones was loosened in part, but the bones were but slightly contaminated. The avulsed portion of the scalp with the hair, had been wrapped in a newspaper and taken along to the hospital. Under local anesthesia the edges of the wounds were cleansed and devitalized tissues were removed, but some of the contused tissues in the anterior area had to be left, for the time being. The flap of the scalp that had been twisted loose was washed in physiologic solution of sodium chloride, after the hair had been removed with clippers and razor. The scalp was then placed on the wound and fastened by sutures. The spurting arteries were not ligated, in order not to injure the supporting vessels of the surrounding area. A drain served to prevent the development of a hematoma under the scalp. A dry bandage induced a light compression and supplied warmth as the avulsed portion of the scalp was entirely cold. After a week the covering bandage was removed and the wound was treated open. The upper layers of skin were changed into dry necrotic crusts, under which the healing process—much as in burns—progressed. Now (six weeks after the operation) the wound area is dry except for a small necrosis of the margin of the skin of the forehead. A new growth of hair has appeared on the shaved surface, which, however, in contrast with the former dark hair, is of an absolutely blond type. It may be seen that an attempt to save tissues that have been completely severed from the body may be successful if the following conditions are fulfilled: youthful age of the patient, ample blood supply in the surrounding area and a prompt operation. As a rule, the possibility of saving a flap that is still connected with the remaining scalp is excellent; the cleansing and the fixation are not difficult. In case of total loss of a portion of the scalp, with exposed bones, nothing can be done but (after hemostasis) to cover the wound the base of which is usually formed of cranial bones covered with periosteum primarily with a Thiersch flap, or, after healing by granulation, to perform a secondary Thiersch operation. In such circumstances, sensitive and deforming scars are left. The foregoing method constitutes an excellent method of avoiding such evils. There have been few successful attempts of this kind reported.

## Marriages

LUCA EUGENE HUMBERT CELENTANO to DR JEAN DE FRANCES HIPPOLITUS, both of New Haven, Conn, July 23  
EUGENE J NIGGORSKI, Corinna, Maine, to Miss Gertrude Twarogowski of Salem, Mass, June 3  
CLARENCE GEORGE OCHSNER, Wabasha, Minn, to Miss Anita Bouquet of Caledonia, in June  
HUBERT H BURROUGHS to Miss Dorothy May Bowers, both of Sioux City, Iowa, July 22  
LOWELL SINN SELLING to Miss Mary Charlotte Paradis, both of Detroit, June 2

## DEATHS

JOUR A M A  
AUG 4 1934

Missouri State Medical Association, past president of the Carroll County Medical Society, aged 65, died, June 14, in St. Luke's Hospital, Kansas City, of coronary occlusion and myocardial fibrosis

Sterling Buckner Ragsdale, Washington D C, University of Nashville (Tenn) Medical Department, 1908, medical superintendent of the Columbia Hospital for Women and Lying-in Asylum, aged 49, was drowned, July 3, when he stepped into a deep hole while wading in the Severn River

Samuel St John Wright, Akron, Ohio, Cleveland Medical College, 1876, member of the Ohio State Medical Association, past president of the Summit County Medical Society, aged 63, many years on the staff of the Children's Hospital, died, May 29, of chronic myocarditis and arteriosclerosis

Edgar C B Mole, Hardeeville, S C, University of Georgia Medical Department, 1894, member of the South Carolina Medical Association president and formerly secretary of the Beaufort County Medical Society, aged 61, died, June 9, in a hospital at Savannah, Ga, of leukemia

Sands Carr Maxson, Utica, N Y, University of New York Medical Department, 1871, member of the Medical Society of the State of New York, for many years on the staff of St Elizabeth's Hospital, aged 85, died, May 13, of strangulated hernia and peritonitis

John B May, New Holland, Ohio, Cincinnati College of Medicine and Surgery, 1873, past president of the Pickaway County Medical Society, for many years member of the board of education, aged 92, died, May 22, of arteriosclerosis and diabetes mellitus

Calvin Carlin Montgomery, Lincoln, Ill, Washington School of Medicine, St Louis, 1900, past president of the Logan County Medical Society served during the World War aged 65, died, May 15, of myocarditis, bronchial asthma and diabetes mellitus

George Andrew Morrison, Bradshaw, Neb, University of Nebraska College of Medicine, Omaha, 1905, member of the Nebraska State Medical Association aged 57, died May 30, in a hospital at York, of cerebral embolism and chronic endocarditis

Rolly Ray Hogue, Linton, N D, Rush Medical College Chicago 1899, member of the North Dakota State Medical Association, served during the World War, aged 58, died June 12, in a hospital at Bismarck, of erysipelas and heart disease

Alexander Tullis, Chicago Jenner Medical College, Chicago 1909, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois 1911, aged 78, died June 28 of lobar pneumonia and benign prostatic hypertrophy

Franklin Francis Carter, Centraha, Kan, Ensworth Medical College St Joseph, 1900, formerly county health officer served during the World War, aged 60, died June 8 in a hospital at Topeka of cerebral hemorrhage and pneumonia

William Elden Casey, Spokane Wash, Beaumont Hospital Medical College, St Louis 1901, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1905, aged 65, died, June 9, of cerebral hemorrhage

John Thomas Whitty, Seattle, Marquette University School of Medicine Milwaukee, 1913, member of the American Urological Association served during the World War, aged 48, died suddenly June 4, of angina pectoris

George Thomas Cooke Adams, St Joseph, Mich Queen's University Faculty of Medicine, Kingston, Ont, 1892, FRCP, Edinburgh LRCS, Edinburgh, L R F P & S, Glasgow, 1892, aged 68, died, June 23 of ruptured gastric ulcer

Laban Benjamin Underwood, Andalusia Ala University of Alabama School of Medicine, 1918, member of the Medical Association of the State of Alabama, aged 39, died, May 13, of injuries received in an automobile accident

Moses O Kupelian, New Britain, Conn, American University of Beirut School of Medicine Beirut Lebanon, Syria 1918, formerly police surgeon aged 37, died, May 13, of chronic endocarditis and pulmonary embolism

James A Davis, Little Rock, Ark, American Eclectic Medical College Cincinnati 1890, Hospital College of Medicine Louisville Ky, 1895, aged 64, died, May 19, of diabetic gangrene and chronic interstitial nephritis

John Irwin Ferguson, London, Ont, Canada Western University Faculty of Medicine, London, 1900, assistant professor of medicine at his alma mater aged 56, died, May 10, in the Toronto General Hospital

## Deaths

Gregorio Maria Guiteras, Senior Surgeon, U S Public Health Service, retired, Yeaddon, Pa, University of Pennsylvania School of Medicine, Philadelphia 1885, entered the U S Marine Hospital Service, now the U S Public Health Service, in 1888 as an assistant surgeon advancing through the various grades to that of senior surgeon, retiring in 1927 with rank of lieutenant colonel, delegate to the Pan-American Medical Congress in Havana in 1902, Guatemala in 1920, Santiago de Chile in 1911 and Montevideo, Uruguay, in 1920, quarantine officer during the intervention of the United States in Cuba from 1899 to 1902, served as sanitation officer of the Seventh Naval District during the World War, aided in the suppression of all the yellow fever epidemics occurring in this country during his career, aged 71, died, July 5, in the Philadelphia General Hospital, of cerebral thrombosis

Charles Aubrey Parker, Chicago, Rush Medical College, Chicago, 1891, member of the Clinical Orthopedic Society, associate clinical professor of orthopedic surgery at his alma mater, past president and secretary of the alumni association of Rush Medical College, chairman of the committee on after-care and study of infantile paralysis of the Visiting Nurse Association of Chicago for which committee he prepared a pamphlet on 'Infantile Paralysis for Parents and Patients', for many years on the staffs of the Home for Destitute Crippled Children, Cook County Hospital and the Presbyterian Hospital, aged 66, died July 16 of pseudobulbar paralysis

Charles Moore Strong, Charlotte, N C, University of Maryland School of Medicine Baltimore 1888, member of the Medical Society of the State of North Carolina, past president of the Mecklenburg County Medical Society, fellow of the American College of Surgeons on the staffs of the Good Samaritan, St Peter's, and Presbyterian hospitals and the Charlotte Sanatorium, aged 72, died, June 14, of heart disease

John W Moore, Houghton, Mich, Detroit College of Medicine, 1895, member of the Michigan State Medical Society, formerly member of the state legislature, aged 62, on the staff of St Joseph's Hospital Hancock, where he died, June 10, of uremia, which developed following an emergency operation to remove a chicken bone which punctured the peritoneum

Henry Brewster Minton, Brooklyn New York Homeopathic Medical College and Hospital 1887, at one time professor of anatomy and medicine at his alma mater for many years member of the state board of medical examiners formerly on the staff of the Cumberland Street Hospital for stomach

William Darrow Runyon, Sioux City Iowa State University of Iowa College of Medicine Iowa City, 1909, member of the American Psychiatric Association served during the World War on the staffs of St Joseph's Mercy, St Vincent's Methodist and Lutheran hospitals, aged 47, died, June 23, of metastatic carcinoma

Harold Samuel Boquist, Minneapolis University of Minnesota Medical School, Minneapolis, 1921, instructor in the department of medicine at his alma mater, on the staffs of the Asbury, Fairview and St Andrew's hospitals, aged 45, died June 12, in the University Hospital, of subacute bacterial endocarditis

Edwin Harrington Musson, Norborne Mo, University of Michigan Medical School Ann Arbor, 1900, member of the

⊕ Indicates Fellow of the American Medical Association

William McKinley Ison, Edmonton, Ky., University of Louisville School of Medicine, 1926, member of the Kentucky State Medical Association, aged 34, died, May 13, of a self inflicted bullet wound

Frank D. Thompson, Fort Worth, Texas, Louisville (Ky) Medical College 1875, aged 82, died, May 18, in the Cook Memorial Hospital of myocardial insufficiency, hypertension and diabetes mellitus

Edgar William Guilford, Newell, W. Va., Western Pennsylvania Medical College, Pittsburgh, 1900, veteran of the Spanish-American and World wars, aged 60, died, May 2, of cerebral hemorrhage

William Paul Owen Thomason, Easton, Pa., Jefferson Medical College of Philadelphia, 1897 on the staff of the Easton Hospital aged 62, died, April 28, of carcinoma of the sigmoid

Muret Napoleon Leland, Minneapolis, College of Physicians and Surgeons of Chicago 1896 on the staff of the Deaconess Hospital, aged 60 died, May 28, of coronary thrombosis

Louis Ignatius Turner, Baltimore University of Maryland School of Medicine, Baltimore, 1877, aged 77, died suddenly, May 9, in Govans, of lobar pneumonia and myocarditis

Howard Iszard, Glassboro N. J. Hahnemann Medical College and Hospital of Philadelphia, 1886, formerly member of the board of education, aged 77, died, May 31, of myocarditis

Stephen Eliud Griggs, Seattle, College of Physicians and Surgeons of San Francisco, 1904 aged 50, died, May 5, of pancreatitis, chronic myocarditis and arteriosclerosis

Granville Lesnar Oldham, Columbus, Ind. Central College of Physicians and Surgeons Indianapolis, 1898 aged 84, died, March 5 of hemorrhage of the stomach

Archie E. Ray, Tullahoma, Tenn., Chattanooga Medical College, 1900, member of the Tennessee State Medical Association, aged 60 died June 4 of heart block

Angela L. Ford Warren, Portland Ore., Willamette University Medical Department Salem, 1877 aged 79 died, May 21 of myocarditis and coronary thrombosis

David Cunningham Blake, Lewiston, Idaho Bennett College of Eclectic Medicine and Surgery, Chicago 1884 aged 81, died, March 27, of lobar pneumonia

Anna Jacobs Green, Chicago, Hahnemann Medical College and Hospital Chicago 1900, aged 62, died suddenly, June 14, of myocarditis and arteriosclerosis

William Addy Oxner, New Brookland S. C. University of Georgia Medical Department Augusta, 1908, aged 64 died, March 22 of influenza and uremia

Arthur J. Griffith, Comer, Ga., University of Georgia Medical Department Augusta 1904 aged 57, died, May 29, of acute dilatation of the heart

Edward Lee Roy Wallace, Los Angeles, California Medical College, San Francisco, 1897, aged 59, died suddenly, June 8, of coronary sclerosis

Thomas John Clayton Tindle, Flinton, Ont., Canada Trinity Medical College Toronto, 1903 died, May 21, in the General Hospital, Belleville

John Patrick Gallagher, Philadelphia, University of Pennsylvania School of Medicine, Philadelphia, 1909, aged 49, died, June 1 of carcinoma

G. Arthur Ferron, Grand Mere, Que., Canada, School of Medicine and Surgery of Montreal, 1900, aged 56, died, April 23 in New York

Lawrence P. A. Magilligan, Brooklyn, Bellevue Hospital Medical College New York, 1893 aged 67, died May 12, of coronary sclerosis

Meyer Jackson, New York, Eclectic Medical College of the city of New York 1887 aged 73 died, April 17 of heart disease

William Van Korb, Philadelphia, Medico-Chirurgical College of Philadelphia, 1898 aged 66, died, April 17, of brain tumor

William A. Miller, Bristol Tenn., Kentucky School of Medicine Louisville 1893 aged 65 died May 4 of pneumonia

William Henry Reader New Amsterdam Ind. Kentucky School of Medicine Louisville 1878, aged 83 died May 25

Louis A. Genest, Legal Alta Canada School of Medicine and Surgery of Montreal Que. 1893 died February 10

Charles E. Gosnell, Bingen Ark. (licensed in Arkansas in 1903) aged 64 died May 28 of nephritis

### YAWS AND SYPHILIS

To the Editor.—The communication of Professor Blacklock of the Liverpool School of Tropical Medicine in *THE JOURNAL*, June 16, page 2043, gives opportunity to correct a typographic error that occurred in my communication referred to by Blacklock in *THE JOURNAL*, January 13, page 148. In this article the second paragraph ends with the sentence "Blacklock proves the proposition that yaws and syphilis are the same thing but quotes the army writers." What I actually said was "quotes the *wrong* writers." This error has caused me no little embarrassment and has been the occasion of numerous letters to army friends in explanation. I therefore welcome this opportunity to broadcast a disclaimer and also to correct several inaccuracies in Professor Blacklock's communication. In order properly to do this it will be necessary to go back a little in point of time.

During April 1932 I received a letter from Dr. N. Hamilton Fairley, joint secretary of the Section on Tropical Medicine of the British Medical Association, of which Sir Leonard Rogers was president, in which I was told that Sir Leonard Rogers was particularly anxious to have me take part in the "discussions on the relationship of yaws and syphilis which is to be opened by Professor Blacklock of Liverpool." This was the centenary meeting of the British Medical Association in July 1932. It was impossible for me to accept this invitation, but I was flattered by this request from so high an authority. This was the first intimation I had that Professor Blacklock was interested in this relationship.

Dr. Blacklock first embraced the hutchinsonian point of view regarding yaws and syphilis so far as I can determine, in 1932, for he first published an article on it in the *Annals of Tropical Medicine and Parasitology*, Oct. 29, 1932. Practically identical material came out in the issue of the *British Medical Journal* for Jan. 21, 1933, and in the November 1933 issue of the *Tropical Diseases Bulletin*. The second publication was devoid of a bibliography.

Properly conducted controversy has a definite place in medical literature. It stops the little publicity seeker in his tracks just as a dum dum bullet stops a savage. It is the rumination of the pseudoscientist trying to get away with his pet fetish. It conserves the best of the forebears. Medicine owes it much. In controversial publications I have always found English physicians generous foemen ready to give and take without malice or misrepresentation.

There is nothing remarkable about the fact that different men when confronted with a given set of premises and thinking logically on them should come to the same conclusions. So it was no surprise as I looked at it that Dr. Blacklock, applying logical thinking to the table of points purporting to differentiate yaws and syphilis, should come to the same conclusions that many physicians before him had arrived at, in trying to explain this intricate question. Sir Jonathan Hutchinson threw the weight of his marvelous intellect and experience on the side of unity and is justly entitled to be called its greatest champion. As pointed out in my editorial, however, this view was held by Thomas Sydenham in the seventeenth century and has been held by many physicians since.

In the early part of 1933 I received several letters from friends stating that Dr. Blacklock had apparently assumed proprietorship of the unity idea. At that time I had seen only the second article by him in which no references were used. When I saw the other two articles I then published the communication in *THE JOURNAL* as a mild protest, not that he had failed to quote me but that most of the authorities whom he

did quote represented the duality idea, which, judged from his three papers, he was opposing. There was no "misapprehension" on my part as to what he had done.

The writer puts an incorrect and wholly unjust interpretation on a quotation he uses from an editorial of mine published in the *American Journal of Clinical Pathology* (2 239 [March] 1934). "Professor Blacklock quotes many more or less important writers along the line of the yaws-syphilis investigations but has little to say about his own countrymen who have borne the brunt of it in defense of what they know to be true. Nor ought but silence has he for the group of Americans, principally U S naval medical officers, who have, by research and writing, defended Hutchinson's view for the past thirty years." He then makes it appear that I had said he had ignored the work of Americans in the yaws-syphilis investigation. Quoting the names of some twenty distinguished American physicians, many of whom I am proud to call my friendly antagonists, and with practically all of whom I have exchanged reprints, he asks for the impossible interpretation he chooses to place on it.

The American authors Professor Blacklock names have, some in their textbooks, some in special researches, either frankly described yaws and syphilis as distinct or have interpreted their investigations as opposed to the views of Hutchinson. I never said that Professor Blacklock has "entirely ignored" Americans. He would have been disingenuous indeed had he failed at this point. What I did imply was that he had no generous reference to the work of those Americans who by research and writing had defended for some thirty years the views of Dr Blacklock's distinguished fellow countryman the late Sir Jonathan Hutchinson, that yaws and syphilis are identical. I intimated too that most of the Americans sharing the unity view are members of the U S Naval Medical Corps. This also is correct. Professor Blacklock's charge of "a very definite misrepresentation" is boomeranged back at him by an unbiased reading of the very sentence he quotes from my editorial.

I believe that those who read this will not be led to the prejudiced verdict that "Dr Butler's remarks are not justifiable," which Dr Blacklock seeks in his final paragraph.

ing U S Naval Hospital, Brooklyn

### SIMPLE TOURNIQUET FOR THE KIDNEY PEDICLE

*To the Editor* — Competition among the professional gadgeteers seems to continue heatedly.

Anticipating all manner of distress and apprehension from hemorrhage, when one has to perform some evacuating or plastic operation on a kidney, he is beset with the thought "Can I control bleeding, after incision into the kidney by the simple measure of a finger scissor hold about the blood vessels, or shall I apply a cushioned clamp or string a catheter about that pedicle and fix the pressure and its retention by a pair of forceps?" He may have to employ all of them.

I offer this suggestion. Use the simple commercial block, double groove and catheter tourniquet, which can be boiled. After the kidney has been disembedded and the pedicle made free, pass the loop of rubber tubing about it, either under vision or by faith, draw an end of the tubing to such a point as will yet permit a long piece or fluff of gauze to be interposed at the block and on its opposite side as well. Then draw the tubing taut until pulsation in the renal artery is no longer felt. The two pieces of gauze both serve as cushions, and the one remote from the grooved block may be used as a tractor for counterextension when release of the instrument may be indicated.

GIDEON TIMBERLAKE, M D, St Petersburg, Fla

## Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted on request.

### TYPHOID IMMUNIZATION AND GASTRO INTESTINAL SYMPTOMS

*To the Editor* — 1 Is it desirable to vaccinate a nurse with typhoid (paratyphoid?) vaccine while she is in daily contact with a typhoid (paratyphoid?) patient? 2 Would the fact that such a nurse was suffering from gastritis and possibly had a gastric or duodenal ulcer contraindicate such vaccination even though it might be otherwise desirable? 3 Would such vaccination accentuate a stomach or duodenal lesion to such an extent as to make a gastro-enterostomy necessary? 4 Would it be ethical for a surgeon to state to a patient on whom he had performed a gastro-enterostomy that it was the result of typhoid immunization and was the basis for legal action against the physician who had vaccinated the patient? Please omit name and address.

M D Kansas

ANSWER — 1 If the vaccination can be completed before the nurse goes on duty, the answer is yes without any qualification. If the nurse is already on duty, two possibilities should be considered. First, the vaccination might make the nurse too ill, at least for a day or two, to care for her patient and, secondly, the vaccination might not be completed until after the recovery of the patient. Perhaps it would be best either to secure a vaccinated nurse or, if that is impossible, to redouble the usual precautionary measures.

2 and 3 The possibility that retching and vomiting following the vaccination, although exceptional, might affect the ulcer disastrously cannot be denied, under such circumstances, gastro-enterostomy or other operation might be necessary.

4 No, it would not be justifiable for a surgeon to state positively that gastro-enterostomy was made necessary by typhoid immunization, because the surgeon cannot know for sure that the condition requiring operation did not develop spontaneously and independently of the immunization. Finally, the surgeon had no right to tell the patient that the immunization was a fair basis for action against the physician who had vaccinated the patient because it may fairly be assumed that the physician in vaccinating the patient acted according to his best judgment in the case.

### SENSITIVITY TO MILK AND CREAM

*To the Editor* — The inability to tolerate milk and cream by undernourished individuals is a serious problem. A common cause of this is an allergic state. In 1912 at the age of 28 I substituted milk for coffee which I had been drinking three times daily. Almost immediately a marked diarrhea developed. This persisted for weeks before the cause was understood. Since that time even small amounts of milk or cream have invariably caused allergic headaches and symptoms of colitis. I had to give up even mashed potatoes because of the milk they contained. Several weeks ago I started taking 4 ounces of cream with one raw egg at night and with my noon meal and in addition three 2 grain tablets of adrenal substance (Parke Davis) daily. The cream is now perfectly tolerated none of the symptoms having manifested themselves. Whether the raw egg, the adrenal substance or sudden change in allergic reaction is responsible for the tolerance future experimentation will clear up.

LOUIS K GUGGENHEIM M D St Louis

ANSWER — Cow's milk is an important antigenic substance (allergen or atopen) in the first few years of life, but its importance rapidly diminishes in later years. So true is this that it is rather uncommon to find any allergic symptoms from milk after the age of 15 to 20, whereas in infancy and early childhood milk is the cause of eczema, asthma, vasomotor rhinitis and gastro-intestinal disorders in a large percentage of cases, the statistics varying from 10 to 37 per cent of all cases. It is also well known that hypersensitiveness to other foods as well as to milk diminishes in most cases as the child grows older.

In this particular patient the milk sensitivity has apparently lasted at least to the age of 28 and brought on gastro-intestinal symptoms, especially diarrhea and allergic headaches (probably migraine). Then milk was stopped (from about 1912 to the present year about twenty-two years) and now cream is well tolerated, no mention is made as to whether milk is now tolerated. It may well be that, after such a long abstinence, both milk and cream may now be taken in moderate amounts. Excessive volumes would probably bring on symptoms again, as the spontaneous "desensitization" that so commonly occurs when such foods are omitted from the diet for long periods is really a "hyposensitization" rather than a total and permanent "desensitization."

## QUERIES AND MINOR NOTES

361

Another reason why cream may be taken where milk may not is that milk contains, on the average, about 4 per cent of protein and 4 per cent of fat, cream averages from 3 to 4 per cent of protein and from 20 to 40 per cent of fat. One uses less cream than milk and hence absorbs much less protein when drinking cream. It is well known that many people who cannot drink milk because of an idiosyncrasy can tolerate diluted cream, i. e., cream diluted with four or five parts of water. This is explainable by the fact that while such a dilution lowers the fat content of the cream from about 20 to 4 per cent it also lowers the protein from 3 to 4 per cent to less than 1 per cent—a percentage which many sufferers can tolerate. It is of course the protein fraction of milk that causes the symptoms, not the fat. The whole phenomenon of milk idiosyncrasy or allergy is dependent on a quantitative sensitivity—each person so afflicted can tolerate varying amounts of milk. Those slightly sensitive can get along by drinking a little milk daily or by substituting cream for milk the next group (more sensitive) can get along by using heated milk (heated to from 150 to 170 F) or powdered milk (some cannot tolerate cows' milk in any form but can get along on goats' milk, and finally, there are some individuals so hypersensitive to milk that milk is a poison to them even in minute quantities. These unfortunates cannot consume vegetable substitutes such as almond, coconut soy bean or poppyseed milk. Most of them can however, tolerate milk from any animal. In the severe cases desensitization to cow's milk, either orally or hypodermically may be necessary. The taking of raw egg with the milk is probably of no significance to the milk hypersensitivity. As a matter of fact almost all students of allergic conditions agree that persons should avoid raw eggs at all times because the eggs are apt to be absorbed too quickly and act as foreign proteins with resultant symptoms. Clinically, many attacks of various allergic conditions have been traced to raw eggs.

The use of the suprarenal substance would likewise seem not to be a factor here. To date no satisfactory results have followed the use of various suprarenal extracts when they are taken by mouth. Their potency seems to be destroyed by the action of the digestive juices. Epinephrine hypodermically is of course, extremely effective in combating bronchial asthma, urticaria and other allergic diseases.

### INJECTION METHOD FOR HEMORRHOIDS

To the Editor—I have seen mention of the use of phenol in vegetable oil for the treatment of hemorrhoids and in view of the following recent observation I am naturally prejudiced against it. I should like to know whether it is an accepted form of treatment. Mr. S took his wife to an irregular practitioner for treatment for piles. She was given an injection of phenol (5 per cent) in vegetable oil. She soon had a serious local disturbance and was taken to a neighboring clinic where it was found that a large slough was developing. Several months later she was still incontinent. At the same time Mr. S persuaded a neighbor Mr. E to go to the same place for treatment and receive a similar injection. Mr. E states that not more than 5 cc was given to the patient. In a few hours serious symptoms developed and on returning to the office he told that he would be all right and to go on home. The next day he was brought in to the local hospital with a good deal of cough much expectoration of frank bloody sputum (bright red) and moderate much mesenteric embolism. The entire time he was in a state of severe shock. Death occurred in about forty eight hours. Autopsy was not obtained. It would seem that the injection treatment of hemorrhoids could be limited to drugs with low toxicity. Would not the oil in itself involve a good deal of danger from the standpoint of embolism?

A C EITZEN M D Hillsboro Kan

ANSWER—The treatments of hemorrhoids with the injection of 5 per cent phenol in vegetable oil is a procedure accepted by many proctologists. Obviously the injection method, whether carried out with phenol quinine or sodium morrhuate, whether as much skill and experience as any operative procedure. One would hardly imagine that an osteopath would have adequate training and experience to realize that external hemorrhoids are not made beneath the submucosa or below the papillary line that internal hemorrhoids are injected only in the absence of fissures or fistulas or that sometimes weeks of conservative treatment together with the dilation of the sphincter may be necessary before injections are undertaken.

The second patient must have died of an embolism. This may have been a fat embolism as the correspondent suggests but in the absence of an autopsy a differentiation between a fat embolism and thrombo embolism is not possible. Rectal operations and even a gentle manual dilation of the sphincter may set up an ascending thrombophlebitis from which a thrombus can be mobilized into either the portal or the caval circulation.

These are apt to occur in the presence of a rectal infection. On the other hand, injections of oily suspensions, such as intramuscular injections of bismuth preparations, have been known to produce fat embolism. The injection method for many years in the hands of itinerant physicians and irregulars, has of late been greatly improved. Proper selection of cases and proper technique will minimize although not absolutely prevent untoward reactions. It must be remembered that no type of surgical operation is entirely without hazard.

### GIANT CELL TUMOR OR SARCOMA

To the Editor—A white woman aged 20 fell in the subway injuring her right knee. Two months later a roentgenogram of the right lower extremity disclosed a sarcoma of the right tibia in its upper portion but outside the knee joint. Biopsy revealed a giant cell sarcoma. The tumor was presumably removed in toto by an operation. This was followed by two series of roentgen exposures—five treatments in each series—which caused considerable swelling and redness of the knee involved. Coley's serum has been recommended to prevent a recurrence. I should like to know 1 The present opinion concerning the use of Coley's serum in such a case 2 Any further treatment you would recommend kindly omit name

M D New York

ANSWER—The age of the patient, the location of the tumor, the thoroughness of the operation and the accuracy of the diagnosis have an important bearing on recurrence in so called giant cell sarcoma or benign giant cell tumor. In a series of about 250 cases of tumors of this type, the recurrences following conservative operation such as excision or curettage have averaged around 30 per cent. Recurrences however are less than 16 per cent in patients under 21. Although the upper tibia is one of the most frequent locations for this form of tumor, it is rarely the site of recurrences, and only 8 per cent of recurrences take place in this location. The operation was complete leaving a bare shell of bone, and should not in all probability be a recurrence at this age and site. If there is a recurrence, the first thing to do is to check the diagnosis by submitting sections or tissue to a competent pathologist. The swelling and redness following irradiation is not unusual and soon subsides. It does not portend a recurrence. Irradiation is not as effective after operation as before operation in curing these tumors.

1 The value of Coley's toxins if any is apparently in sarcoma. Giant cell tumor is no longer looked on as sarcoma by those who have made a careful study of the disease.

2 Further treatment would not seem to be indicated unless recurrence takes place. Should this happen, further excision and thorough cauterization and filling of the cavity with bone chips would be the method of choice.

The most important safeguard against recurrence in this case is to check the microscopic diagnosis. Occasionally a sarcoma with giant cells is mistaken for benign giant cell tumor microscopically. The history in this case resembles that of a typical benign giant cell tumor.

### GIARDIA INFESTATION

To the Editor—In case of infestation of the biliary tract with Giardia does the infestation extend up into the smaller bile ducts and radicles or is it essentially a gallbladder infestation? Will the removal of the gallbladder eliminate the infestation from the bile tract? How frequently in vivo does Giardia undergo division? What is the most successful treatment? Please omit name

M D Indiana

ANSWER—There is insufficient evidence to give satisfactory answers to any of these questions. The surgical removal of the gallbladder in a few cases has demonstrated infection of the gallbladder, but just how far the infection extends is not known. Similarly the effect of removal of the gallbladder in such infections is not known. There are no data on the rate of division of Giardia within the body. In fact, although division of the flagellates in the intestine must occur and although the process of longitudinal division of free flagellates has been described it has been seen only a few times. Division within the cysts is of course common and some investigators have suggested that the increase of the parasites in the intestine may be due to the hatching of such cysts before they leave the body—a condition that would be quite unlike other intestinal protozoa. A large number of drugs have been used in giardiasis, including bismuth compounds, emetine, thymol and various arsenicals but none of these have found general acceptance and most workers believe that there is no satisfactory treatment. The apparent disappearance of the flagellates after such treatments may be due to the tendency of the organisms to disappear spontaneously from the stools at intervals. Furthermore the improvement in symptoms that are ascribed to the treatment may be due to nonspecific effects of the drugs used and to

general hygienic measures associated with treatment. As an example of the many treatments that have been used, the following is that of McClendon (*California & West Med* 34 266 [April] 1931), who worked with children. Bismuth salicylate was given by mouth in doses of from 0.3 to 0.65 Gm daily for ten days and was followed by a rest period of one week. Then treparsol was given by mouth in doses of from 2 to 4 grains (0.125 to 0.25 Gm) twice daily for ten days. A second or even as many as four courses of treatment were sometimes given, with rest periods of a week after each course. Presson reports successful clearing of stools in two out of three cases of *Giardia* infestation by the oral administration of carbarsone, 0.25 Gm twice a day for ten days. The unsuccessful case was a boy of 13 who retained the organisms despite several courses of carbarsone with intervening rest periods. Of the two arsenicals, treparsol has not been accepted by the Council on Pharmacy and Chemistry and carbarsone stands accepted for New and Nonofficial Remedies.

#### WATER BALANCE AND CONVULSIONS

To the Editor—I have recently received a Mosenthal report on a patient as follows:

Time	Volume	Specific Gravity	Urea		Chlorides	
			Per Cent	Gm	Per Cent	Gm
8 to 10	82	1.030				
10 to 12	75	1.030				
12 to 2	89	1.072				
2 to 4	84	1.074				
4 to 6	45	1.037				
6 to 8	48	1.037				
Total day	423 cc		2.6	11.0	1.22	5.2
Total night	337 cc	1.031	2.58	8.6	0.4	1.3
Total	760			19.6		6.5

I assume that the usual twenty-four diet of about 1,500 cc of fluid was given. A phenolsulphophtalein test was done as follows:

First hour	82%
Second hour	15%
Total	97%

(The dye was given intravenously.)

Blood urea nitrogen was 14.2

Blood cholesterol was 200

Blood phosphorus was 3.4

Blood sugar 96

Blood chlorides 485

Blood carbon dioxide 72

I have never seen a Mosenthal test show such a fixed high specific gravity. Also I do not think there is enough urine in the day total or sufficient chlorides excreted. I may add that the routine urinalysis showed a specific gravity of 1.036 but otherwise was negative. Clinically there are no urinary symptoms or signs of edema. The only disorder is occasional signs of cerebral irritation (convulsive movements). Do you think this case could substantiate the water balance theory of convulsions that water and chlorides are being retained and so cause convulsions and the diminished output of necessity has high specific gravity? Or could an early preedema stage of nephritis be present? The laboratory calls these reports all normal. Please comment on them as I think there is some significance present. Please omit name.

M D, New York

ANSWER—The fact that the laboratory data are normal with the exception of the low daytime water excretion and low chloride output is inconsistent with renal changes, since albuminuria and edema are presumably absent. It might therefore be wise to investigate the possibility of other routes by which water and chlorides may be lost, namely, excessive perspiration, vomiting and diarrhea.

#### FEVER REACTION AFTER OPERATION

To the Editor—What fever reaction should be expected in class A hospitals following abdominal operations in which the infection has not extended beyond the organ removed? What is the upper limitation of fever before one should consider it an infected case due to contamination? What percentage of abdominal operations become infected because of contamination in well regulated hospitals? Please omit name.

M D, Texas

ANSWER—Following an abdominal operation without infection there may be a fever of 100 F for three or four days. If the fever persists or increases, one may suspect serum retention or infection. If the fever reaches 101 for more than one day with local symptoms of inflammation, some infection would be expected. It is rare for infection to develop in the abdomen even with the opening of the stomach or small intestine.

Infection of the subcutaneous tissues occurs in about 5 per cent of all abdominal operations, in most hospitals. It may occur from contamination, through opening the intestinal tract or removing infected organs, by spread of skin bacteria, from mouth or nasal droplets or dust, or from dust in the air in the operating room. Good surgical technic will largely eliminate

the first two, and the wearing of nose and mouth masks the third, while the last will be a rare source in a good hospital.

The peritoneum is more resistant than the subcutaneous tissues, and some lack of proper technic should be expected as the cause of infection unless the operation has opened up grossly infected tissues, when contamination would be difficult to avoid.

Naturally, a bacteriologic study should be made of all infections. It will help to determine the cause and frequently aid in the treatment.

It is assumed that all sterilization of supplies should be checked bacteriologically as indicated.

#### ACTINOMYCOSIS OF TONGUE

To the Editor—A farmer consulted me in March for a sore on the tip of his tongue. This little sore was somewhat alarming as about eight years ago I had performed a rather radical operation for a carcinoma of the lower lip. But as this sore was only of two weeks' duration it was cauterized with silver nitrate. According to the patient's report it healed in a few days. April 1 he consulted me for an enormous swelling of the tongue which made speech and swallowing quite difficult. It did not interfere with respiration. He had previously made the correct diagnosis of his illness. He was suffering from what he called wooden tongue. About six months before he had lost a valuable bull from this disease so he was familiar with the symptoms and the contagious character of the spores or actinomycosis. Iodine potassium was prescribed in heroic doses with marked diminution in the size of the tongue after the prescription had been taken for a few days. April 5 he had a severe chill accompanied by extreme prostration; the pulse was 130, temperature 103 and respiration 30. A marked consolidation was found in the apex of the right lung. He rallied that day. In the forenoon of the following day he expressed himself as feeling extremely well and both pulse and temperature were near normal. He persisted in reading the newspaper which was permitted. In the afternoon of that day he suddenly died while the nurse was changing his pillows. There was no autopsy. No blood count was made at the time of the office examination or during the acute illness. I will be pleased if you could send me any information concerning this disease.

J E ENGSTADT M D Grand Forks, N D

ANSWER—Undoubtedly the patient had actinomycosis of the tongue, but the exact nature of the acute febrile condition that developed April 5 with marked consolidation in the apex of the lung obviously cannot be determined at this time. Usually actinomycosis of the lung does not develop so acutely; the clinical picture suggests lobar pneumonia.

#### UTERINE SUSPENSION OPERATION

To the Editor—What is the statistical evidence regarding the success or failure of the uterine suspension operation? Kindly omit name.

M D Missouri

ANSWER—In a narrow sense, the "uterine suspension operation" refers to the Olshausen round ligament suspension and kindred procedures. The Olshausen operation has not enjoyed great popularity, but it was the favorite of Graves in cases presenting retrodisplacement and almost invariably gave excellent results in his hands.

Uterine displacement operations, as ordinarily done, have been credited with recurrence of the displacement in 50 per cent of the cases. During recent years, however, it has been realized that this operation must be performed with painstaking care and that suturing of the uterosacral ligaments for additional support is an essential feature of the repair in most cases. A carefully performed uterine displacement operation, together with suturing of the uterosacral ligaments and posterior leaves of the broad ligaments, gives a permanently satisfactory result in nearly all cases, even in women who undergo pregnancy and labor thereafter.

#### BRONCHIECTASIS AND CONTINUOUS EXPOSURE TO SULPHUR DIOXIDE

To the Editor—I have under my care a man who is suffering from a moderate degree of bronchiectasis in both lungs. He is a service man for a mechanical refrigerating company and is frequently exposed to sulphur dioxide fumes. Could such fumes independent of any other cause produce such a bronchial condition? There is a possibility that this patient would be eligible for industrial insurance compensation if it could be proved that his lung condition came from the gas. What is the effect on pulmonary tissue including the bronchi of long continued intermittent exposure to the different gases used in mechanical refrigerators? Please omit name and address.

M D Ohio

ANSWER—Whatever answer is made to this query, there will be many who will stoutly hold opinions to the contrary. The conditions under which exposure is provided to irritant gases in warfare have led to a wide belief that these gases act intensely during a period of acute injury but that sustained

damage is unlikely. In industry the form of exposure may be quite dissimilar. There the concentrations are (or may be) so low as to attract little attention except among new workers and visitors. These low concentrations, however, are continuous or oft repeated. The respiratory tract protects itself by increased secretions, but low grade inflammation continues. In the case of sulphur dioxide, more damage is done to the upper portions of the respiratory tract, but the lower tract does not wholly escape. Bronchitis and bronchiolitis may occur. The action of bacterial agents appears to be facilitated by long exposure to irritant gases in the respired atmosphere. Asthma is known to have arisen. In short, long continued or oft repeated exposures to various irritant gases, including sulphur dioxide, are credited with the possibility of harm to the pulmonary tract. Bronchiectasis ensuing on this chronic inflammation along the air passages within the lungs is within reason. It is most difficult to procure exact proof distinguishing a bronchiectasis proximately caused by sulphur dioxide from one caused by the ordinary sources of this condition.

#### USE OF ARTIFICIAL EYE

*To the Editor*—A man, aged 24 had a corneal ulcer of the right eye when he was an infant aged 6 months. As a result of negligence the sight of the eye was destroyed and a repulsive scar appeared. The eye also sunk in a bit and a strabismus developed. Two years ago an eye specialist operated on him in an effort to straighten the eye and to tattoo the scar. The operation was a failure. The eye doctor then advised him to wear a shell (a glass eye). The glass eye he got is thin and it moves well from the center to the left but it does not move from the center to the right. This makes him appear cross eyed when he looks toward the right. I may mention here that the natural eye although sightless, does move freely in all directions. The optometrist who made the glass eye says that it is impossible to make the glass eye move more freely. Do you agree with him? (I cannot see why a glass eye if properly made should move freely from the center to the left and not move freely from the center to the right.) The glass eye often causes irritation. An eye wash consisting of horic acid sodium bichlorate, camphor water and distilled water is used three times daily and it does not help much. What can be done here? Kindly omit name.

M D, Pennsylvania

**ANSWER**—Possibly the temporal half of the artificial eye is so large that motion toward the right of the center line is impossible. Again it is possible that the shell does not fit accurately enough over the shrunken eye to follow it in all directions, in other words the eye rotates underneath the shell. An expert artificial eye maker could in all probability make a shell that would fit accurately and overcome that difficulty. If not, it might be wise to enucleate or eviscerate the eye and thus provide a smaller stump for the shell to rest on.

If the shell causes irritation, it is an indication that (1) the shell is cracked, (2) that the conjunctiva is infected or (3) that the shell strikes the sensitive cornea and causes an erosion. A better fitting shell would probably eliminate that difficulty.

#### PERIODIC PAIN IN THE EYE

*To the Editor*—Please send me information in regard to treatment of periodic pain in the eyeball (right). The patient says that the pain is cramplike in character and wakes him from a deep sleep. It is not aggravated by writing or reading and the eye is perfectly normal as soon as the pain leaves. The pains are now more frequent than they used to be and they prevent him from working. Morphine and heat are the only things that relieve him. The patient referred to is a man aged 44. Physical examination gives negative results. The eyes are corrected with glasses and no focus of infection can be located. This trouble has been bothering him for five years and he has visited eye specialists with no results except that they tell him it is eye strain and give him new glasses. Please do not publish my name.

M D Georgetown, S C

**ANSWER**—If the patient has had a careful examination of the fields and a study of intra-ocular tension so that glaucoma can be definitely ruled out, the most probable cause of the condition is a ciliary spasm. This condition produces all the symptoms mentioned and is relieved by the instillation of 1 per cent atropine sulphate four times a day for four or five days. If the patient's work will not permit the use of atropine in the two eyes at the same time the treatment can be used in one eye at a time, an interval of two and one-half or three weeks being allowed to elapse before the atropinization of the second eye. This treatment may have to be repeated. While the patient is under complete cycloplegia refraction should be done and the full correction prescribed. Ciliary spasm is frequently provoked or aggravated by a vertical phoria and this condition should be either ruled out or corrected with a lens. In the transactions of the Pan American Medical Association Section of Ophthalmology, 1933 appears an article on this subject by Louis Bothman.

### Idaho April Examination

Hon Emmitt Pfost, commissioner of law enforcement, reports the oral and written examination held in Boise, April 3-4, 1934. The examination covered 13 subjects and included 130 questions. An average of 75 per cent was required to pass. Five candidates were examined, all of whom passed. Seven physicians were licensed by endorsement. The following schools were represented:

School	PASSED	Year Grad	Per Cent
College of Medical Evangelists	(1925) 80	(1931)	88
Northwestern University Medical School		(1934)	87
University of Nebraska College of Medicine		(1933)	87
University of Pennsylvania School of Medicine		(1931)	90

School	LICENSED BY ENDORSEMENT	Year Grad	Endorsement of
College of Medical Evangelists	(1932) California	(1933)	Oregon
Northwestern University Medical School		(1925)	Penna
Kansas City Medical College Missouri		(1905)	Washington
University of Oregon Medical School		(1932)	California
University of Pennsylvania School of Medicine		(1931)	Utah
Marquette University School of Medicine		(1932)	Wisconsin

### Nevada May Report

Dr Edward E Hamer, secretary, Nevada State Board of Medical Examiners, reports the written examination held in Carson City, May 7, 1934. The examination covered 11 subjects and included 110 questions. An average of 75 per cent was required to pass. Two candidates were examined, both of whom passed. Two physicians were licensed by reciprocity. The following schools were represented:

School	PASSED	Year Grad	Per Cent
University of Nebraska College of Medicine		(1933)	81 3
Hahnemann Med College and Hospital of Philadelphia		(1902)	82 7

School	LICENSED BY RECIPROCITY	Year Grad	Reciprocity with
College of Medical Evangelists		(1933)	California
University of California Medical School		(1932)	California

### Puerto Rico March Examination

Dr O Costa Mandry, secretary, Board of Medical Examiners, reports the written and practical examination held in San Juan, March 6 1934. The examination covered 15 subjects and included 80 questions. Two candidates were examined, both of whom passed. The following schools were represented:

School	PASSED	Year Grad	Per Cent
Tulane University of Louisiana School of Medicine		(1929)	80 1
Tufts College Medical School		(1933)	83 5

## Book Notices

**Studies on the Possible Intoxicating Action of 32 Per Cent Beer** By A J Carlson N Kleitman C W Muellerberger F C McLenn H Gul Ilekken and R B Carlson Paper Price 75 cents Pp 85, with 10 illustrations Chicago University of Chicago Press 1934

Is beer containing 32 per cent of alcohol by weight intoxicating in fact? The answer can be predicted yes or no as soon as the definition of "intoxicating in fact" is declared. Carlson and his five associates accepted as a definition of "intoxicating in fact" a beverage which contains alcohol in such proportion that, when consumed in the quantity which may practically be drunk by the ordinary man, it will produce a condition commonly known as intoxication or drunkenness. The answer is quite obviously yes, and one wonders at the reasons for going to such pains to demonstrate the obvious. Even in the exquisite work of Benedict and Dodge, and of Miles, one will find no more sincere effort to make observations of an objective character and well controlled after the best scientific manner than are those reported by Carlson and his co workers. These results confirm the 1922 observations of Miles in the matter of the relation of urine alcohol to blood alcohol. The authors record an excellent chemical and statistical technique, on the whole superior to the psychologic aspects of the study.

One is readily convinced of the truth of the finding that the consumption of two bottles of beer (275 cc of alcohol) on an empty stomach in fifteen minutes did not cause intoxication as defined, and in the adults tested. Also the reader will readily admit that twice the amount (546 cc of alcohol) in twice that time did not produce intoxication as defined. Furthermore, the drinking of a bottle of beer each hour for sixteen consecutive hours (208 cc of alcohol), or one bottle every forty minutes for eight consecutive hours (164 cc of alcohol), or even a bottle every thirty minutes for eight consecutive hours (208 cc of alcohol), did not in the adults tested cause alcoholic intoxication, as defined. Finally, one is not surprised to learn that five of the twenty-nine persons tested did comply with the definition of intoxication proposed by a committee of the U S Senate when the beer was drunk at the rate of from four to six bottles an hour for three and one-half hours (from 109 to 191 cc of alcohol), and that vomiting occurred when 32 per cent beer or "near beer" was drunk at this rate. The question which the physiologists and their associated scientists put to themselves is answered unequivocally. It is well to have such meticulous honesty of purpose and method presented in so straightforward a manner.

The hope expressed in the preface by the senior and much respected author is not likely to be answered since any definition of alcoholic intoxication for practical convenience today must be as far removed as to threshold of occurrence and delicacy of criteria as the driving of a 1934 Ford differs in personal and public responsibility from buggy riding in 1834. We are not concerned except as a matter of decency and public manner with the kind of intoxication the Senators defined. Persons as drunk as that are obviously and soon disqualified from participation in the responsibilities and privileges of the public way. The question that is in process of being answered in the public courts of Sweden and Germany is how the intoxicating effects of alcohol which slows the reaction time of the commonly trusted neuromuscular mechanisms of sight, hearing, touch, to hand and foot, can be recognized in time, and before they have progressed to the advanced and crude state of general muscular incoordination and emotional irresponsibility, commonly known as intoxication or drunkenness.

Miles in his classic Carnegie Institution Bulletin 333 "Alcohol and Human Efficiency" did in fact ten years ago test the effects of smaller amounts of alcohol than Carlson and his co workers have just reported on, and he revealed with a conclusiveness equal to that of the Carlson study that the depressant, i.e., toxic, effects of alcohol could be demonstrated in the absence of the state of drunkenness as commonly known and as defined by the committee of the Senate.

It cannot but be a matter of regret to those who look up to university departments of physiology that so much time and skill were spent to make observations that can hardly apply as

guides to human conduct in this day of speed and power, when the machine easily masters the man if the man is not completely master of himself. Avoiding the drunkenness of earlier decades by the evidence of Carlson's thirty six subjects will not suffice for the motorists of today.

The moderate impairment of function accompanying the low blood and urine alcohol reported in this study is not always, or necessarily different from behavior mismanagement which comes from illness or loss of sleep. That fact no more excuses us if we describe the effects of small amounts of alcohol as normal or nontoxic than if we declined to consider behavior disturbances of fatigue and fever as abnormal.

It can be predicted with reasonable certainty that the generations which follow us will continue the tendency of our contemporaries and predecessors to be more critical in the use of the term "alcoholic intoxication" and define it more in terms of blood content than in ability to "navigate."

**Die pathologisch histologischen Untersuchungsmethoden** Von Professor Dr C Schmorl Lehr Medizinalrat und Direktor den patholog anatom. Abteilung am Städtischen Krankenhaus Dresden Friedrichstadt Herausgegeben von Professor Dr P Geipel Sixteenth edition Paper Price 30 marks 1/p 469 Berlin F C W Vogel 1934

This marks the last of a series begun by the author in 1897. The task of revising and bringing all the material down to date was practically complete, when the author contracted a wound infection in his laboratory, which caused his untimely death. This edition was issued under the editorship of Professor Geipel, one of Schmorl's oldest students. The work has been and still is the most authoritative and well written on the subject in any language. It is unusually complete and is written in a clear and concise manner. It has been so practical and helpful that few technicians or pathologic laboratories even in this country have been without a copy. There are few books on methods of pathologic histology in which practically all the desirable information is as available as in this short treatise. It is hoped that Professor Geipel will perpetuate this book as a memorial to his illustrious teacher.

**Obstetric Medicine The Diagnosis and Management of the Commoner Diseases in Relation to Pregnancy** Edited by Fred L Adair M A M D F A C S Mary Campau Byerson Professor of Obstetrics and Gynecology University of Chicago and Edward J Stieglitz M S M D F A C P Assistant Clinical Professor of Medicine Rush Medical College of the University of Chicago Cloth Price \$8 Pp 743 with 24 illustrations Philadelphia Lea & Febiger 1934

The two authorities who present this book, Adair, an obstetrician and Stieglitz, an internist who has had extensive experience with obstetric patients, secured the assistance of a large number of other specialists to help in its preparation. An attempt was made to select individuals who had had an opportunity to acquire some of their special knowledge in connection with pregnant women. The contributions, which cover almost every form of medical complication, show evidence of careful preparation and skilful editing. It is difficult to discuss in particular any of the thirty-seven chapters, because they are all excellent and present both the obstetric and the medical point of view. It is unfortunate that there was not included a chapter on cancer of the cervix complicating pregnancy, especially because such cases are more common than the rare tropical diseases to which a chapter is devoted. The book should be in the library of every physician who either practices obstetrics or sees pregnant women in consultation. It will be of inestimable assistance to the practitioner whose patients cannot afford the services of a specialist or who practices in sparsely settled districts where there are no specialists.

**Nauchnaya literatura SSSR Sistematicheskiy ukazatel knig i zhurnalnykh statey 1928** Meditsina Komitet po zavedyvaniyu uchenymi i uchebnymi uchrezhdeniyami pri Ts I K S S R Komissiya po sostavleniyu i izdaniyu indeksov nauchnoy literatury [Scientific Literature of Russia Systematic Index of Books and Periodicals for 1928 Medicine Commission for Compiling and Editing Indices of Scientific Literature for Central Executive Committee of Russia] Cloth Price 15 rubles Pp 1478 Moscow Gosudarstvennoe slovarno entsiklopedicheskoe izdatel'stvo Sovetskaya entsiklopediya 1931

The preface informs the reader that in May 1928 the Soviet of Peoples Commissars of the Union of Socialist Soviet Republics decided, in the interests of systematization of information in scientific matters to issue an annual index embracing all

branches of knowledge. The publication is to consist of five volumes (1) Social Sciences, (2) Natural History, (3) Agriculture, (4) Technic and (5) Medicine. The first volume, on Medicine, appeared in 1931. The material is selected from the entire literary output of the Soviet Union. A brief annotation appears below the book or the article quoted stating as briefly as possible the problem, the method, the results achieved and the main conclusions. The use of the volume is facilitated by a subject and author appendix. The text is in Russian and in German. The paper is of good quality, the print is clear, and the general appearance of the volume is attractive even when judged by our standards. The value of a publication of this sort is too self-evident to call for special comment.

*Die Abwehrkräfte des menschlichen Körpers und die Möglichkeit der therapeutischen Beeinflussung.* Von Dr. med. Andreas Wertheimann, a. o. Prof. und Prosektor der pathologischen Anatomie der Universität Basel. Paper. Price 8.80 marks. Pp. 128. Leipzig: Curt Kabitzsch, 1934.

This book aims to give the practicing physician and the student an introductory summary of present knowledge of the reactions of the body to infections and injuries. Phagocytosis, natural resistance, acquired immunity, allergic phenomena, local reactions to injuries, and the possibility of therapeutically influencing the protective reactions are the main topics. The book is based on certain selected works, mainly by teachers of the author, and the presentation is rather hurried and more or less fragmentary, but in the main it follows the current teachings.

*The Chances of Morbid Inheritance.* Edited by C. P. Blacker, M.C. M.A. M.D., General Secretary of the Eugenics Society. Cloth. Price 7s. Pp. 449 with illustrations. Baltimore: William Wood & Company, 1934.

This compilation by eighteen English writers, is a distinctly valuable condensed reference book which should be highly useful to physicians confronted with problems in genetics and faced with the necessity for giving advice as to marriage and procreation under circumstances that may well prove disastrous for adviser and advised alike if the advice given is not based on demonstrated scientific facts as well as on common sense. The book contains a chapter on genetic principles and separate chapters on the hereditary nervous diseases, epilepsy, mental disease, heredity in diseases of the eye and of the ear, heredity and allergy, blood diseases, disease of the cardiovascular system, kidneys, skin and digestive tract, disorders of the thyroid gland, diabetes and renal glycosuria, tuberculosis, neoplastic diseases and congenital abnormalities of the skeleton. An appendix is devoted to methods of analysis of pedigrees. There is a glossary of genetic and psychiatric terms, especially useful to the lay reader who may seek this book for information. A schedule for recording pathologic pedigrees is shown. The book is well written. The judicial approach of the writers to disputed or obscure questions is notable throughout. Excellent bibliographies follow the several chapters. It is a serviceable and constructive contribution to the literature of applied genetics.

*Essentials of Medical Electricity.* By Elkin P. Cumberbatch, M.A. B.M. D.M.R.E., Medical Officer in Charge, Electrical Department and Lecturer on Medical Electricity, St. Bartholomew's Hospital. Seventh edition. Cloth. Price 10/6. Pp. 508 with 147 illustrations. London: Henry Kimpton, 1933.

The book does not deal with all the medical uses to which the electric current has been put but limits itself to a consideration of the galvanic (direct) current and its modifications, the high frequency currents (medical and surgical diathermy) and the static currents. The author covers these fields with a thoroughness developed by many years of practical experience in the electrical department of St. Bartholomew's Hospital, London. The issuance of a seventh edition of this authoritative work permits the author to elaborate on the enlarged field of usefulness of the high frequency currents. This book, like others covering the same subject, indicates clearly the need for the establishment of a nomenclature that is agreed on universally. Many workers, for example, would prefer to see the term dispersive applied to describe the less active of two electrodes rather than the term indifferent, which is used in the book. The volume can well be recommended for the beginner and for the more advanced student in medical electricity.

It is an excellent effort to combine the therapeutic data gleaned from the empirical observations of many years with scientific explanations of the physics of medical electricity and with the limited existing knowledge of its physiologic responses when applied to the animal organism.

*Chronic Nasal Sinusitis and Its Relation to General Medicine (Chronic Sinusitis and Systemic Sepsis).* By Patrick Watson Williams, Hon. Consulting Surgeon in Diseases of the Ear, Nose and Throat, Bristol Royal Infirmary. With a foreword by Sir Humphry Davy Rolleston, Bart. G.C.V.O., F.R.C.S. Physician Extraordinary to H.M. the King. Second edition. Cloth. Price \$5. Pp. 262 with 122 illustrations. Baltimore: William Wood & Company, 1933.

This work is interesting and will well repay reading, though the reader will hardly agree with many of the author's ideas. In the first place there are a good many rhinologists who do not believe that the nose acts as a focus of infection often if at all. Infections of the nasal sinus mucosa are usually on the surface. They differ in this respect from infections deep in tonsillar crypts or at the roots of teeth. Furthermore, it is difficult to believe that the fewer the symptoms an infected sinus produces the more likely it is to act as a focus for serious diseases.

The normal nasal mucosa has bacteria which dwell there as their constant habitat. This is, as every one knows, just as true of the pharynx and the nasopharynx. Their presence should not be wrongfully construed. Not only are bacteria found here at all times but there has been no serious study made as to the normal density of the bacteria present in these portions of the anatomy. As it is not known in what numbers they are present in conditions of health, the puncturing of a sinus and the recovery of clear or only slightly cloudy fluid, producing on culture a certain number of bacterial colonies, should not be taken as proof that these sinuses are acting as a focus for disease in distant parts of the body. The accessory nasal sinuses, no different from the nasal mucosa, are on good authority thought to contain bacteria at all times, even though their number may not be large. It would, indeed, be strange if bacteria could not wander from the nose where they dwell normally into the sinuses from time to time.

No one has suggested the widespread removal of pharyngeal mucosa or of that of the septum and turbinates because these places harbor bacteria. The mucosa of the nose reacts precisely as does that of the sinuses to repeated or constant infections and in the same manner. Yet the mucosa of the nose has never been considered a source of disease in far distant parts of the body.

The enthusiasm with which the idea of focal infection was greeted several years ago appears to be waning to some extent, at least in this country. Every one recognizes the truth behind the notion, but the original furor is surely dying down. One of the most prominent exponents of the theory of focal infection in this country in recent years was heard to lament the unnecessary slaughter of tonsils and teeth occasioned by his pioneer work in this respect.

An interesting revision of opinion seems to be taking place regarding retrobulbar neuritis, a condition commonly ascribed to a focus of infection. Herein on slight provocation, and with bacteriologic and roentgenologic evidence, none of them often of the strongest character, radical operations have frequently been performed. From the Mayo Clinic come figures that are highly interesting. In more than 500 definitely proved cases of multiple sclerosis, 60 per cent of the patients presented themselves with a history of nasal sinus operations because of visual disturbances, the largest number of which fell in the class of retrobulbar neuritis. In other words, a patient suffering from early multiple sclerosis, who has visual disturbances, has an excellent chance of having a nasal operation.

Credit must be given the author for his conservative surgical treatment at least in cases which to some would present disputed evidence of sinusitis. He does not engage in the widespread extirpations of bone and mucous membrane that some have seen. A logical follow up of the focus of infection idea with respect to nasal sinusitis would be at least an attempt to remove every vestige of diseased mucous membrane and bone, and here many fine workers are of the opinion that even in

those instances in which radical surgery is fully justified one cannot expect to cure a proportion of one's cases

The author's careful description of methods of examination are to be commended, and he does well to call attention to the need for careful technique in the determination of the presence of nasal infections

**Persons One and Three A Study in Multiple Personalities** By Shepherd Ivory Franz Cloth Price \$2 Pp 188 New York & London Whitticsey House McGraw Hill Book Company Inc 1933

This book is a record of an interesting case of dual or triple personality in a man mentally affected by war experiences and subsequent excitations. As is to be expected in a record of this kind there are some repetitions but they do not become tedious or impair the general action because they are necessary in the presentation of the history of the patient to connect the different episodes into a presentable sequence. Franz does not pretend to offer any psychologic or psychoanalytic explanation of his case and does not aim at making any dramatic impression, but he presents a faithful relation of the history as he uncovered it in a contact of two years with the man he studied, during which time he succeeded in restoring almost completely his patient's original personality. The book makes agreeable reading and is worthy of notice by those interested in such subjects

**Une nouvelle syphilis nerveuse. Ses formes cliniquement inapparentes.** Par Paul Ravaut médecin de l'Hôpital St-Louis Paper Price 45 francs Pp 203 with 3 illustrations Paris Masson & Co 1934

The title of this book will prove disappointing to readers familiar with the modern conception of neurosyphilis. What Ravaut presents is an excellent account of the evolution of this conception during the past thirty years, with almost exclusive reference to the work of the brilliant group of Parisian investigators, chief of whom were Ravaut himself, Fournier and Vidal. By the "new" neurosyphilis he means the condition generally designated "asymptomatic neurosyphilis," the existence of which is revealed and its course determinable only by detailed study of spinal fluid reactions over a period of years. In 1903 Vidal and Ravaut found such hidden involvement of the spinal fluid in 68 per cent of cases of secondary syphilis. Ever since, Ravaut has occupied himself assiduously with the study of this spinal fluid infection, which may remain permanently latent, may disappear or may evolve with manifest disease. It calls for energetic treatment from the beginning.

**Survey of Public Health Nursing Administration and Practice** By the National Organization for Public Health Nursing Katharine Tucker General Director Hortense Hilbert Assistant Director for the Survey Cloth Price \$2 Pp 262 New York The Commonwealth Fund London Oxford University Press 1934

This survey is a storehouse of information about public health nursing. It is symptomatic of the most important force now working in public health fields, namely, self appraisal. An evaluation of one's own virtues and faults can be either a complacent and self-satisfied glorification of one's own profession or specialty, or it can be a searching probe into the shortcomings of that profession, together with a fair acknowledgment of its accomplishments. Happily, this is the latter. Based on a sampling of the nation-wide field, conclusions are presented from a study of public health nursing in twenty-eight urban and rural communities, in which were found twenty-one public health nursing organizations of a private character, eighteen departments of health, eighteen boards of education, four industrial nursing services, three insurance company nursing services, two tuberculosis associations, one university teaching district and one children's clinic. The conclusions in brief are that effective public health nursing service requires efficient administrative direction, better qualifications of field personnel, crystallization of organization policies through written guides or manuals, adequate provision for the health of the staff, student affiliation, adequate financing, satisfactory community relationships, especially medical, and improvement of performance in certain types of field service. The recognition of the necessity for medical advice to the nursing organization as such is important, this must be distinguished from medical advice to clients of the organization, which has always been recognized as a prerequisite before any

nursing service could be rendered by a properly constituted organization for public health nursing. The attitude of physicians is described as usually friendly or at least tolerant but in some instances antagonistic. When the nursing profession succeeds in getting more of its field work into the hands of better prepared public health nurses and when the principles set forth in this survey are practiced as universally as they should be, the attitude of the medical profession will tend to grow more and more friendly. In the meantime, all nursing organizations working ethically with physicians should be encouraged by the friendly cooperation of the medical profession. This book should be valuable in placing the public health nurses, as a group, on record again in favor of well conceived and ethically practiced public health nursing.

**Seeing and Human Welfare** By Matthew Luckiesh D.Sc. Director Lighting Research Laboratory General Electric Company, Nela Park Cleveland Cloth Price \$2.50 Pp 193 with illustrations Baltimore William & Wilkins Company 1934

Here is a complete sketch of seeing, presented in a non technical manner and well presented. The author has been working and writing on the psychology of vision for years basing his writings on elaborate investigative work of a most ingenious character. Much of this is touched on lightly in this book and there are ample references to the original publications for those who are interested. The book is divided into eight chapters of some twenty pages each. Wisely but little space is devoted to the technicalities of the eye and the diseases of that organ that interfere with full vision. The factors that influence the visual perception of the surrounding world are discussed at length and the necessity of proper illumination is stressed. The illustrations are for the most part photographic and many are extremely ingenious in their concept. The ophthalmologist will not find much new in this book, but the public at large can benefit definitely by a careful study of this account of "the new science of seeing."

**Die parasagittalen Meningeome** Von Dr. H. Olivecrona Paper Price 24 marks Pp 144 with 145 illustrations Leipzig Georg Thieme 1934

The author has presented his experience with thirty-four cases of intracranial meningioma arising along the sagittal sinus. The material is presented in an interesting, clear and concise manner. Following a brief introductory chapter in which the frequency of meningiomas in general and their incidence in different portions of the cranial cavity, particularly along the superior longitudinal sinus, is discussed, the author presents a summary of each of his thirty-four cases. He describes each case briefly, pointing out its peculiarities, any clinical, pathologic or physiologic points of particular significance, and any errors of diagnosis or treatment that might have been made. The sixth chapter is concerned with the gross pathology of these particular tumors, the author having intentionally omitted any discussion of the cellular pathology of the tumors themselves, apparently leaving that for a future report to be made by the pathologists. The seventh and eighth chapters are concerned with the symptomatology and differential diagnosis. In the last chapter the author presents his operative technique, which is comparable to that seen in the better neurosurgical clinics of this country, a discussion of the post operative complications that occurred in his cases, and the results of his treatment, 15 per cent died following operation, 10 per cent died later of recurrence, 50 per cent were completely recovered, and 25 per cent recovered with some neurologic defect. Olivecrona feels that these figures can be greatly improved and that the operative mortality should be reduced to 5 per cent or less. It is a pleasure to read a monograph such as this, in which the author, who has had extensive experience in his field, discusses in a lucid manner all phases of tumors of one particular type, in one location. As the author states in the preface there are in neurologic literature numerous studies concerned with the symptomatology of tumors of various parts of the brain but all too few that take into consideration the nature of the neoplasm whereas the picture produced by a brain tumor is as much a matter of the type of tumor as of its location. Such studies as this advance our knowledge in this field and will always find a welcome with every one interested in the subject of intracranial neoplasms.

## Medicolegal

**Revocation of License to Practice Medicine**—The Illinois Department of Registration and Education instituted proceedings to revoke Schireson's license to practice medicine.

The department charged that Schireson was not a man of good moral character when he obtained his license, that he employed fraud, deception and unlawful means in applying for and obtaining it, and that he was guilty of gross malpractice, resulting in the permanent injury of a patient. After a lengthy hearing, the record of which includes 2,000 pages of evidence, the department revoked the license. The superior court, Cook County, quashed a writ of certiorari to review the order of revocation. Schireson appealed to the Supreme Court of Illinois.

The Illinois civil administrative code, as amended,<sup>1</sup> defines the procedure to be followed in revoking a license. So does the Illinois medical practice act.<sup>1</sup> Only the medical practice act, however, states the causes for which a license may be revoked. The civil administrative code leaves to the Department of Registration and Education the determination of the causes for revocation. The department proceeded in this case under the code, apparently assuming that the causes for revocation named in the medical practice act were applicable in proceedings under the code. The Illinois Supreme Court, however, held otherwise.

The legislature said the Supreme Court, cannot delegate to any department, officer or commission the power to legislate or to invade the province of the judicial department. It cannot vest in officers not constituting a part of the judicial system the power, at their discretion, without rules or standards for the exercise of such discretion, to determine what the law shall be. That portion of the act which attempts to confer on the Department of Registration and Education authority to determine what constitutes a *prima facie* case against a licensee, without laying down any code of ethics, rules or regulations, violation of which shall be legal cause for the revocation or suspension of a physician's license, is an unwarranted delegation of legislative authority. It gives the department no jurisdiction or authority to determine what complaint, together with evidence, documentary or otherwise, constitutes a *prima facie* case.

In justification of the action of the Department of Registration and Education, it was apparently contended that the causes for which the department might suspend or revoke a physician's license were set forth in the medical practice act of 1923 and that the amendment to the civil administrative code under which the department proceeded should be read in connection with the medical practice act. The medical practice act of 1923, said the court, is a complete act and provides a complete code of procedure for the institution, hearing and determination of charges against a physician, looking toward

the revocation or suspension of his license. The act of 1927 purports to amend the civil administrative code, it in no way purports to amend or repeal the medical practice act of 1923. If in order to proceed under the act amendatory of the civil administrative code the department had to refer to the medical practice act of 1923, then the act amendatory of the civil administrative code would be an act to amend also the medical practice act. The title of the act amendatory of the civil administrative code contains, however, no suggestion or intimation that its purpose is to amend the medical practice act. But section 13 of article 4 of the constitution of the state of Illinois provides that no act shall embrace more than one subject and that that subject shall be expressed in the title. As applied to physicians, therefore, said the court, the act of 1927, purporting to amend the civil administrative code, is unconstitutional.

Although the Supreme Court held that the act of 1927, under which the Department of Registration and Education had proceeded, was unconstitutional so far as related to the practice of medicine it discussed at some length the charges that had been preferred against Schireson.

The charge that he was not, when he obtained his license, a man of good moral character, could not stand. The medical practice act, said the court, definitely states the causes for which a physician or surgeon may be deprived of his license, and the fact that a man is not of good moral character is not stated among them. Furthermore, the medical committee, reporting to the Department of Registration and Education, defined good moral character as follows: "The term 'good moral character' as used in this connection is assumed to pertain to the entire sphere of human conduct as coming within the description of right and wrong, the obligation of duty and ethics." There is no human frailty or weakness which is not covered by this definition, adopted by the committee as one of the basic principles of law under which Schireson was tried. We are of the opinion, said the court, that this standard of good moral character as applied to a proceeding of this nature is entirely too broad and sweeping to be made the basis of a conviction founded on the charge of a lack of good moral character and requires a much higher test than is usually applied to the ordinary accepted meaning of the term.

The medical committee adopted this same definition of good moral character in passing on the charge that Schireson was guilty of the employment of fraud, deception and unlawful means in applying for and securing his license to practice medicine. It is apparent, said the court, that the legislative intent, as expressed in the medical practice act, contemplated some positive, wilful or intentional act to be committed on the part of the registrant, which actively induced the issuance of his license. It must have been some overt act in the way (1) of wilfully making false answers to material questions affecting his qualifications for the practice of his profession, or (2) of unlawfully concealing from the department the fact, if it was a fact, that he had theretofore been guilty of conduct stated in the statute as grounds for the suspension or revocation of a license, or (3) of some wilful misconduct in taking an examination, such as having some one else write his examination for him, or wilfully cheating in an examination. The proposition of law adopted by the medical committee as the basis of what constitutes good moral character and the alleged fact that Schireson, when he applied for a license, was not a man of good moral character and was therefore guilty of fraud and deception in obtaining his license are unique. In the opinion of the court, however they could not rightly be classed as fraud or deceptive practice on the department in obtaining the license, within the meaning of the law.

Schireson was charged with gross malpractice, resulting in the permanent injury of a patient. No question was raised, the court points out, as to the constitutionality of conferring on the Department of Registration and Education authority to decide what constitutes gross malpractice, and the court therefore did not pass on its constitutionality. Mere malpractice is not a ground under the medical practice act for the revocation of a physician's license before his license can be legally suspended or revoked he must be found guilty of gross malpractice. It is clear, said the court, that the report of the medical committee was based on the legal proposition that the law demanded of Schireson by reason of some statement or advertising on

1 The Illinois civil administrative code of 1917 created a Department of Registration and Education (Smith Hurd's Rev. Stat. 1933, ch. 127, sec. 4) and transferred to it the rights, powers and duties theretofore vested in the state board of health relating to the practice of medicine (ibid. ch. 127, sec. 58). The department was thus charged with the duty of issuing licenses to practice medicine. By an act approved July 7, 1927 (ibid. ch. 127, sec. 60c; Laws 1927, p. 858) the code was amended so as to provide that: "Certificates may be revoked or suspended in the manner provided by this Act and not otherwise. The Department may upon its own motion and shall upon the verified complaint in writing of any person provided such complaint or such complaint together with evidence, documentary or otherwise presented in connection wherewith shall make a *prima facie* case investigate the actions of any person holding or claiming to hold a certificate. The word 'certificate' as defined by the act (ibid. ch. 127, sec. 60b) covers licenses to practice medicine. Under this amendatory act a licensee against whom proceedings are instituted is entitled to a hearing after due notice before a medical committee made up of five medical practitioners designated by the director of registration and education (ibid. ch. 127, sec. 60a) constituting a permanent medical advisory and examining board for the department. On the basis of the findings of this committee (ibid. ch. 127, sec. 60a) the department was authorized to revoke licenses. As to the causes for which licenses might be revoked the civil administrative code as amended by the act of 1927 was and is silent. The medical practice act however (Smith Hurd's Rev. Stat. 1933, ch. 91, sec. 116x; Laws 1923, p. 426) four years before the amendment to the civil administrative code discussed above authorized the suspension and revocation of licenses to practice medicine and defined the procedure to be followed to that end. Under that act no person can be cited for such a hearing except on a sworn complaint setting forth the particular act or acts charged against him (ibid. ch. 91, sec. 16b). A person so cited is entitled to a hearing before the Department of Registration and Education. The act contains no provision for the appointment of a medical committee to conduct such hearings. The grounds on which licenses may be suspended or revoked are stated in the act and include gross malpractice resulting in permanent injury or death of a patient, and the employment of fraud, deception or any unlawful means in applying for or securing a license or certificate or in passing an examination (ibid. ch. 91, sec. 16a).

his part, a much higher degree of skill and ability than is expected of the average physician. If this is a correct rule we would have varying degrees of skill required when a charge of malpractice is made either in a civil suit for damages or in a proceeding to revoke or suspend his license. Under such rule, a specialist treating a patient professionally might do or omit to do some act the doing or omission of which would constitute gross malpractice on his part, which would not even be deemed negligence on the part of the average, ordinary physician in the same community. The degree of professional skill required of a physician might be made to depend on the extravagance or boastfulness of his statements as to his skill and ability. We do not believe said the court that it can be seriously contended that such is the law in the state of Illinois.<sup>2</sup> The law in Illinois is that a physician is required to possess, and in his practice to use reasonable skill—not perhaps, the highest degree of skill that one learned in the profession may acquire, but reasonable skill such as physicians in good practice ordinarily use and would bring to a similar case in that locality. The standard adopted by the medical committee and the department with respect to gross malpractice, the court held to be erroneous.

The principles and procedure that must be followed in the suspension and revocation of licenses were summarized by the Supreme Court as follows:

The power to revoke the license of any professional man is not arbitrary or despotic to be exercised by any board, commission or department according to its pleasure or whim. A license to practice medicine in this state strictly speaking is not a property right yet it is a privilege or right which is of great property value to the holder thereof. To qualify in the first instance for the obtaining of such license has cost any applicant years of arduous study and work and the outlay of a considerable sum of money. A license having been obtained according to the provisions of the statute the holder of a license can only be deprived of it in accordance with the law of the land not at the mere discretion of some department or board. The license being a valuable right the owner before he can be deprived of such right is entitled to a full and complete hearing held in accordance with the statute. Where the hearing to revoke a license of any professional man is not before a court judicially convened it may be more or less informal. The niceties and refinements of the procedure or the forms of questions to and the answers of witnesses are not so strictly applied as on a hearing before a judicial body but the substance of the law must be at all times regarded as well as the competency and materiality of the evidence. The correct rules of law applicable to the issues must be observed and followed at the hearing before the commission or body hearing the cause. No higher legal tests are permitted to be adopted by the body trying the case than the law of the state recognizes as the correct tests to be applied to the issues being tried. The burden of proof never shifts to the license holder but the burden remains throughout the hearing upon the department or body making the charge. The necessity for the strict enforcement of these salutary rules is particularly required where the charges often originate with the board, department or commission sitting as the tribunal upon the trial of the charges. The guilt of any defendant of the charges made in the complaint against him must be established clearly and conclusively by competent evidence before the license of any defendant may be legally revoked. The body hearing the case should be a qualified body without prejudice and strictly impartial as to the issues to be tried. Not to apply these rules of law to hearings of this character would be to deprive a defendant of the due process of law guaranteed to him by our State and Federal Constitutions. Const. Ill. art. 2 §2 Const. U. S. Amend. 14. The proceeding must be an orderly one conducted in accordance with established rules which do not violate the fundamental rights of the defendant. It is a well recognized fact that to deprive a professional man of his license to practice his chosen profession is generally the death of his professional life.

The judgment of the superior court was reversed and the cause remanded with directions to enter judgment for the defendant, *Schireson—Schireson v Walsh (Ill.) 187 N. E. 921*.

**Malpractice Death of Child and Infection During Childbirth**—The plaintiff sued the defendant physician, alleging that through his negligence in treating her during confinement and delivery she was lacerated and infected and her baby was killed. From a judgment for the patient, the defendant appealed to the Supreme Court of Alabama. Pending the submission of the appeal she died and her personal representative was substituted as plaintiff.

The defendant contended that damages were not recoverable for the prenatal injury or death of an infant. As we con-

strue the complaint, said the Supreme Court, the plaintiff asks damages not for the death of the child or for prenatal injury to it but only for the mother's pain and anguish caused by such death or injury. If the mother suffered physical or mental pain because of the death of her unborn child, and that death resulted from the negligence of the defendant, the plaintiff is entitled to damages. Moreover, as long as a child is in its mother's womb it is a part of the mother, and for any injury to the unborn child, damages are recoverable by the mother. *Deutch Admr v Inhabitants of Northampton* 138 Mass. 14 52 Am. Rep. 242, *Stanford v St. Louis San F. R. Co.* 214 Ala. 611, 108 So. 566.

The trial court refused to instruct the jury that there was no duty on the part of the defendant physician to send his patient to the hospital, either before or after the delivery of the child, that the law presumes the exercise of a reasonable degree of care and skill by a physician, and that the issue before the jury was not whether the mother was injured, but whether the defendant possessed reasonable skill and was reasonably diligent, and not negligent, in treating his patient. The refusal of the trial court to give such instructions, the Supreme Court held to be correct.

Malpractice cases, said the Supreme Court, must be determined largely on expert testimony. The burden of proving negligence is on the plaintiff. Proof that the mother sustained injury in the birth of her child does not prove that that injury was the result of negligence. Nor does the fact that infection followed the delivery of a child warrant an inference of negligence, when it appears from expert testimony that medical science has found no way absolutely to prevent infection. The doctrine of *res ipsa loquitur*, said the court, does not apply to cases such as this one. A physician, in the absence of a contract to the contrary, does not insure a successful operation or a cure. Reasonable and ordinary care, skill and diligence are required of him, such as physicians in the same general neighborhood, in the same general line of practice ordinarily have and exercise in like cases and under like conditions. When a physician has fulfilled these requirements he has discharged his duty, and the fact that good results do not follow cannot be made the basis for recovery of damages.

The Supreme Court held the verdict of the jury to be contrary to the weight of the evidence, reversed the judgment of the trial court, and remanded the case for a new trial—*Snow v Allen (Ala.)*, 151 So. 468.

<sup>2</sup> The rule here announced seems to be contrary to the rule followed by the courts of last resort in every other State in which this question has arisen. A note in the American Law Reports Vol. 59 page 1071 cites cases in eleven jurisdictions holding that a physician who holds himself out as having special knowledge and skill in the treatment of some particular organ or disease is required to exercise that degree of skill and care ordinarily possessed and used by similar specialists and that his duty to his patient is measured by a higher standard of skill than that of a general practitioner but cites no cases to the contrary.

## Current Medical Literature

### AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (\*) are abstracted below.

**Infection in Rheumatic Cardiovalvular Disease**—Rothschild and his associates made a study of 161 persons dying with evidence of rheumatic heart disease past or present. Of the 161 cases studied 106 showed evidence of an active infection and of these 103 ended fatally as the result of circulatory failure. The occurrence of heart failure in the first five decades of life in persons who have a valvular defect can be attributed in the majority of instances to an active infection of the myocardium rather than to the degree of the mechanical defect. It is striking to note the high grade of mechanical defect existing in persons living even to the fifth and sixth decade with little or no evidence of congestive failure. In a few instances complete quiescence of the rheumatic myocarditis was present as early as the second decade of life. The number of the quiescent cases increased considerably in the later age periods. Circulatory failure in the later decades of life in persons presenting valvular defects was found in the majority of cases to be precipitated by the expected contributory causes occurring at this time of life, viz hypertension either in the systematic or pulmonary circuit atherosclerosis of the coronary arteries, coronary thrombosis myocardial degeneration and fibrosis.

**The Electrocardiogram in Experimental Myocardial Infarction**—According to the studies of Wilson and his associates, ligation of the septal branch of the left coronary artery in the dog is usually followed by infarction of a large part of the ventricular septum. Immediately after this vessel is obstructed the electrocardiogram shows displacement of the RST segment of the ventricular complex. Later disturbances of intraventricular or atrioventricular conduction develop. Right bundle-branch block occurred in all three experiments. In one instance the right branch block complexes were not strikingly different from the complexes usually obtained after the right branch of the bundle of His has been cut in spite of the fact that a large part of the septal muscle was dead. In right bundle-branch block the precordial electrocardiograms may be characteristic in every respect when the standard electrocardiograms are not. Under these circumstances precordial leads are of great value in locating the conduction defect. When the potential variations of the precordium are small the precordial electrodes should not be paired with a single electrode but with a central terminal connected through like resistances of 5000 ohms or more to all three extremity electrodes. The R deflection of the levocardogram is not abolished by infarction of the septum but is frequently absent in lead I after

ligation of the anterior descending and in lead III after the ligation of the circumflex branch of the left coronary. This deflection is not of septal origin. The muscle responsible for the preliminary deflections of the levocardogram is widely distributed, and it is probable that most of the endocardial surface of the left ventricle is active before the first summit of the levocardogram is written.

**Initial Complex of Electrocardiogram After Cardiac Infarction**—Winternitz reports fifteen cases and cites twenty-six from the literature in which characteristic changes appeared in the initial complex following a coronary closure. The changes may be classed in three groups. In the first one finds a modified form of left axis deviation with small  $R_1$  and deep  $S_2$  and  $S_3$ . The characteristic of group two is the negativity of the principal deflection of all leads whether this is S or Q. The third group is recognized by the shrinking of all the main waves while smaller deflections may persist unchanged. The anatomic basis for the first two groups is an extensive necrosis of the anterior wall of the heart. For the third group it is necrosis of anterior and posterior walls as a result of two thromboses. Controlled by a series of 1460 electrocardiograms chosen at random, these changes were found to be not pathognomonic but most suggestive of the presence of infarct of the heart. They occur less frequently than do the heretofore recognized signs of coronary thrombosis, but they may be present in those cases in which there are no characteristic changes in the final complex. As interpretation of the QRS changes a disturbance of the muscular balance of the two sides of the heart caused by the cutting out of a large mass of muscle is brought forward but the possibility remains that for each group there is a localized disturbance of intraventricular conduction.

**Ablation of Normal Thyroid in Angina Pectoris**—Weinstein and his associates observed the immediate post-operative relief of pain in the chest after total thyroidectomy in nineteen patients. Data were collected before and during several weeks after operation in patients showing changes in nonanginal precordial pain changes in areas of skin hyperesthesia and muscular and periosteal hyperalgesia of the chest wall and changes in the character and distribution of pain of angina pectoris. Within a few hours after operation nonanginal precordial pain, hyperalgesia and hyperesthesia disappeared and remained absent from two to four weeks but then usually reappeared if the basal metabolic rate had not

declined significantly. Only after the basal metabolic rate had dropped appreciably did the foregoing signs and symptoms disappear permanently. Studies were made on the distribution of the pain of angina pectoris produced under standard conditions in three cases before and after hemithyroidectomy. The remaining half of the thyroid was removed at a later date. Exercise within two weeks after hemithyroidectomy produced no pain in the arm and the side of the chest corresponding to the side of operation. The pain of angina pectoris was experienced only on the unoperated side and usually stopped at the midline of the sternum. The authors discuss the similarity of these observations to those after cervical sympathectomy and alcohol injection. The basal metabolic rate did not change appreciably after the first hemithyroidectomy. From two to eight weeks after operation, pain on exercise was again experienced on the operated side. Only after removal of the other half of the thyroid and after an appreciable drop in the basal metabolic rate was the pain of angina pectoris relieved permanently. From these observations the authors conclude that the immediate relief of pain after total thyroidectomy is due to the interruption of afferent nerve impulses from the heart at the time of operation, that relief by this mechanism is only temporary, and that permanent relief is related to the lessened work of the heart attendant on the development of the hypothyroid state. Complete rest in bed should be enforced after total ablation of the thyroid despite the early subjective relief experienced by the patient, until the basal metabolic rate is lowered significantly.

**Arteriosclerosis of the Lumbar Segmental Arteries**—According to Reichert and his associates, the ordinary intermittent claudication in the arteriosclerotic patient is characterized by pain, which is attributed to physiologic processes developing in the working muscles easily fatigued as the result of impaired blood supply. It is associated with a lack of arterial pulsation in the feet and ankles, color alterations in the skin of the extremities on change of posture and roentgenographic evidence of calcification in the arteries of the legs. Intermittent claudication because of weakness in the thighs and hips was the chief complaint of four nonsyphilitic arteriosclerotic patients, who exhibited a spastic gait resembling that of a tabetic patient, who had no positive neurologic signs and whose roentgenograms revealed calcification in the lower abdominal aorta. The claudication of the thighs in these four patients was attributed to ischemia of the spinal cord produced by alterations in spinal branches of the arteriosclerotic lumbar segmental arteries arising from the abdominal aorta. This hypothesis was strengthened by roentgenographic evidence of calcification in the terminal portion of the abdominal aorta and by experimentally produced claudication in the thighs of adult dogs after occlusion of the lumbar segmental arteries without interference with the blood supply to the thighs or remainder of the lower extremities, as shown roentgenographically by complete arterial injections of the animals. Unilateral claudication developing after ipsilateral occlusion of one or more lumbar arteries in the dog afforded further proof that ischemia of the spinal cord was the cause of the claudication.

**Neutropenia Developing During Amidopyrine Medication**—Rawls presents two instances of neutropenia developing while the patients were taking amidopyrine. One patient returned to normal nine days after the drug was omitted without any other form of treatment. After a period of rest the amidopyrine was resumed. This was followed by neutropenia after the patient had received about the same amount of the drug as on the previous occasion (280 grains [182 Gm]). The leukocyte count returned to normal in eight days, or about the same time as after the first attack. The rapid recovery after the omission of the drug, in one instance without therapy and in the other with only four injections of 10 cc each of pentnucleotide would seem to indicate that the neutropenia was probably produced by the amidopyrine. Although the second patient was taking a combination of magnesium carbonate and amidopyrine, the fact that the first patient had two attacks of neutropenia after the use of amidopyrine alone eliminates any probability that magnesium might have played any part in the condition. A predisposition to neutropenia may have existed in these patients, or the onset may have been

due to the inability of the bone marrow to cope with any additional strain that may have been brought on by the amidopyrine. Neutropenia is frequently periodic in character and may be produced by several factors, as pointed out by Beck. Farley reviewed thirty-nine cases appearing in the literature in which the function of the bone marrow was depressed following the use of various preparations of arsphenamine. Taking these into consideration and recognizing that benzene is a powerful leukocytic depressant, it is possible that amidopyrine, a benzene derivative, could be an etiologic factor. The authors, two cases occurred in a series of 200 patients receiving the drug. In two other patients, the polymorphonuclear counts were reduced from 55 and 60 per cent to 35 and 40 per cent, respectively, while amidopyrine was being taken, but the counts promptly returned to normal when the drug was omitted. Two others in the series had nausea, vomiting, exhaustion and pyrexia, but blood counts were not obtained. It is possible that these cases may have been similar to the two reported cases and that recovery may have occurred spontaneously when the drug was omitted.

**Experimental Production of Edema and Elephantiasis**—Drinker and his co-workers describe three typical instances of lymphatic obstruction in the hind leg of the dog. Similar changes have been produced in four other animals. Obstruction has been brought about by repeated central cannulation of

lymphatic trunks with injection of a suspension of crystalline silica and a 25 per cent solution of quinine hydrochloride. Lymphedema developed after such injections and eventually became pronounced. The protein content of the edema fluid rose slowly to above 4 per cent. With the establishment of lymphedema the subcutaneous connective tissue increased and the leg gradually became elephantiac. In the presence of chronic lymphatic obstruction the part became susceptible to attacks of acute infection. A hemolytic streptococcus has been isolated from the edema fluid early in these attacks. The seizures were exactly like the attacks that occur in human cases of lymphedema and elephantiasis.

**Sterilization of Females**—Burch advocates a method for the sterilization of women that is not a major surgical procedure. It is preferable to cesarean section when the chief indication for cesarean section is sterilization. Under these circumstances the operation for sterility is carried out from two to three months after normal labor. The patient is placed in the exaggerated lithotomy position. The cervix is exposed and seized with a cervical hook or forceps. A semicircular incision is made behind the cervix from 1 to 1½ inches in length and the peritonium is opened. A crushing forceps is placed across the tube three-fourths inch from the fimbriated extremity. The tube external to the crushing forceps is removed and a silk ligature is tied securely in the groove made by the crushing forceps. The same procedure is carried out on the opposite side. This procedure leaves the tubes in good shape for a plastic operation for restoration of their lumen provided the patient's condition improves to the point at which pregnancy would not be a menace to life. Should the disease for which the sterilization is carried out be incurable, the author advises the method of Medlener which consists of applying a crushing clamp to a loop of the tube the application of a silk ligature in the groove and excision of the tube distal to the ligature. In cases in which the uterus is high lying and with little mobility the approach may be made through the anterior fornix. The patient is propped up in bed at the end of twenty-four hours placed in a chair at the end of forty-eight and allowed to leave the hospital within from

four to five days from the time of operation. A Rubin inflation test of the tubes should be carried out annually for the first two years following any operation for sterility. Sterilization as an operation alone should not be carried out unless birth control methods are not applicable.

**Vaginal Hysterectomy in Cancer of Fundus of Uterus**—Horsley believes that the strongest indication for vaginal hysterectomy is cancer of the fundus of the uterus. He gives a technic combining several features from other operations. The vagina is painted with a 50 per cent solution of tincture of iodine and the uterus is packed with a strip of iodoform gauze soaked in the same solution. The cervix is closed with stout silk, so burying the iodoform gauze in the uterus. Since adopting this precaution the author has had only one case of peritonitis in 148 vaginal hysterectomies. This precaution also lessens the chances of implantation of cancer cells in the vault of the vagina. An incision is made around the cervix, and from the middle of the anterior portion of this incision a straight incision is carried down the anterior vaginal wall for about 2 inches. The bladder is dissected up with blunt or gauze dissection from the anterior vaginal wall and from the anterior surface of the uterus. The anterior peritoneum is opened and then the posterior peritoneum, though in retroversion this may be reversed, and both broad ligaments are clamped in sections and divided. Usually the division of the left broad ligament is completed first, the fundus is delivered into the vagina, and the remaining portion of the right broad ligament is clamped and divided from above downward. The tubes and ovaries are removed if indicated. The clamped sections of the broad ligaments are controlled by transfixing and tying them with plain catgut. These knots should be secure, no double hitch is made, and the first loop of the knot is held with mosquito forceps while the second loop is run down. Each ligature is tied three times and two ligatures are placed on top of the broad ligament. All ligatures are left long and are brought together on each side in a cable. The peritoneum over the bladder is sutured to the peritoneum over the rectum with a continuous mattress suture of 00 tanned catgut. The incision in the vaginal mucous membrane is closed with a continuous suture of number 1 tanned catgut, the ligatures should emerge from each end of the incision. Three or four strips of iodoform gauze are packed in the vault of the vagina, and the two cables of the ligatures are tied over them. At the end of twenty-four hours the cables are cut, and in forty-eight hours the gauze is removed.

**Sympathetic Ganglion Block in Arterial Aneurysm**—Gage states that blocking the sympathetic ganglions preliminary to the treatment of aneurysms of the peripheral arteries is valuable. The development of a collateral circulation by other methods is rather tedious is not without danger, and requires time for the development of the collateral circulation. He does not believe that the compression method should be neglected. Therefore he advises that in the treatment of all aneurysms of the peripheral vessels one of the first surgical procedures that should be performed in preparation for direct attack on the aneurysm is interruption of the vasoconstrictor fibers supplying the blood vessels of the extremity involved. As this can be done by the method advocated by Flotow, by the use of alcohol to destroy the ganglion, he believes that this procedure is without danger. In conjunction with block of the lumbar sympathetics or cervical sympathetics he advocates the use of the Matas compressor, which would facilitate the development of a collateral circulation. He reports a case of mycotic aneurysm of the common iliac artery in which there was a rapid development of the collateral circulation by blocking of the lumbar sympathetics and in which ligation of the common iliac artery was done near its origin from the aorta, the internal and external iliac arteries were involved and there was a high degree of endocarditis. The patient made a complete recovery without any complications.

**Diagnosis and Treatment of Hemorrhagic Purpura**—Pemberton points out that a study of the morphology of the formed elements of the blood film, by a competent hematologist is essential to accurate diagnosis of hemorrhagic purpura. Giffin's classification of hemorrhagic purpura permits of accurate designation of the stage as well as of the severity of the disease and therefore fulfils the requirements of a practical

method of grouping the cases for clinical consideration. Splenectomy often has proved a life saving measure by initiating almost immediate remission of the disease which in 63 per cent of the cases has been permanent. In 35 per cent the remission has been followed by one or more episodes of mild bleeding. In only one case has the disease recurred in the acute form. The operative hazard in the chronic form of moderate severity is nominal and in the acute incipient and in the acute recrudescence form the mortality rate is 18 per cent. The indications for splenectomy vary according to the stage and severity of the disease. In cases of incipient and chronic hemorrhagic purpura of mild degree splenectomy is rarely indicated. Splenectomy is definitely indicated in practically all chronic cases of moderate severity. For all acute incipient and acute recrudescence cases, splenectomy should be performed as soon as it is apparent that the course of the disease cannot be checked immediately by medical treatment for delay of operation may prove disastrous.

- Multiple Benign Tumor Like New Growths of Skin Report of Case T. Butterworth Reading Pa.—p. 893

**Amyloidosis of the Skin and Muscles**—Reviewing some cases Michelson and Lynch emphasize the age of the patients—from 46 to 66 years. The initial symptom is progressive weakness, which went on to prostration in their patient. Purpuric lesions, especially at points of frequent minor trauma are common. This is probably due to injury of the small walls of arterioles by the amyloid deposit. In their patient purpuric spots were constantly present on the hands and the tongue and they believe that the severe intestinal hemorrhage may be accounted for in the same way. The marked constipation and fecal incontinence toward the end may be explained by the fact that the intestinal musculature was involved in this type of amyloidosis as in almost every patient examined after death. Tuberculosis and syphilis were excluded, as was malaria. The significance of Bence-Jones proteinuria in the authors' case is not entirely clear to them. Bence-Jones protein is rarely found in diseases other than multiple myelomas. In comparing the Bloch and Glaus case with theirs, they found no resemblance in the cutaneous observations but could conceive of the condition which they described as being the form of amyloidosis cutis observed in Koenigstein's second case in which atrophic changes followed involution of a papular eruption. As in their case, Bloch was unable to demonstrate multiple myelomas during life although in both cases careful roentgen studies were made because of the finding of Bence-Jones proteinuria. The amyloid deposits observed at necropsy in the earlier case were similar to those usually present in systematized amyloidosis and were probably similar to those in the authors' case. The important difference was Glaus's opportunity to examine bone marrow at necropsy and demonstrate myelomatous changes. He regarded the amyloid deposits as the results of toxic changes brought about by the myelomas, and that was the conception of most investigators who observed amyloid in patients with myelomas. This theory is reasonable in that other blastomas (and leukemia carcinoma and Hodgkin's disease) occasionally produce amyloidosis. The difference lies in the fact that the latter processes are associated with

the usual form of generalized amyloidosis, while the myelomas are associated with amyloid deposits of the nature of those observed in systematized amyloidosis, the resemblance being most striking in Bloch's case. More accurate studies on the relationship of myelomas, Bence-Jones proteinuria and systematized amyloidosis may lead to a demonstration of the essential differences between generalized and systematized amyloidosis or toward an understanding of the basic principles of the entire problem of amyloidosis.

**Precipitation Tests for Syphilis**—Ritchie and his associates performed the Hinton tube precipitation test and the Kline and Rosenthal microscopic precipitation tests with careful clinical control and found all three tests to be satisfactory. They do not believe that their advantages would justify substitution of one of them for the Kahn test which is performed on all serums in their clinic. They believe that the Kolmer test gives information not obtainable by any precipitation test. On the other hand, the precipitation reaction will often be positive when the complement fixation reaction is negative. The precipitation test is especially useful in cases in which the serum is anticomplementary by the complement fixation test. It is not merely advisable, but imperative, that a complement fixation test and a precipitation test be performed on each serum.

**Value of Sensitization Tests in Dermatology**—Mendelsohn presents the results of an allergic study of 262 cases of various dermatoses—eczema, urticaria and dermatitis venata (80 per cent of the cases) and prurigo, erythema multiforme, angioneurotic edema and neurodermatitis—in which sensitization tests were performed so that their value could be determined. The results indicate that 1. Intradermal tests are of little value in demonstrating the cause of cutaneous diseases. 2. A great number of positive intradermal reactions are obtained, but they are rarely of practical significance. 3. Positive reactions to food substances or inhalants administered intradermally in patients with cutaneous diseases are far less specific than similar reactions to pollens in patients with hay fever. 4. The indiscriminate subjection of patients with dermatoses to a large number of skin tests is not justifiable. Far greater etiologic help can be obtained by securing a proper history and making a correct dermatologic survey. 5. Patch tests are of decided value, especially in cutaneous diseases that are due to external irritants.

- \*Improved Operative Technique for Suppuration of Petrous Apex M. C. Myerson H. W. Rubin and J. G. Gilbert New York—p. 699

**Operative Technique for Suppuration of Petrous Apex**—Myerson and his associates outline an improved operative technique for the approach to the apex of the petrous portion of the temporal bone by way of the middle fossa. The preexisting mastoid wound is enlarged. A vertical cutaneous incision is made from the uppermost attachment of the auricle about 2½ inches (6.35 cm.) upward. A large section of the squamous bone is removed. This removal of the bone extends down to the zygoma anteriorly and to the knee of the sigmoid sinus posteriorly. The area removed is approximately 4 cm. in diameter. In addition, the tegmen of the mastoid is removed and also a part of the tegmen tympani as far as the prominence of the superior semicircular canal. Elevation of the temporal lobe is first carried out along the anterior surface, hugging the superior border of the pyramid. In the process of separation some resistance is encountered along the superior border from the prominence of the superior canal inward as far as the internal margin of the internal auditory meatus. The resistance is lessened as this point in the separation is reached. At the same time this point marks the beginning of the apical area. The exposure permits inspection of the epitympanic space and of the region of the external and superior

semicircular canals posteriorly for the presence of fistulas. After the inspection and search for a fistula a gouge of appropriate size with a squarely cut off end, beveled on the inside and with the distal end at an angle of 135 degrees from the shaft is placed at a point slightly external to the beginning of the second depression and on the anterior surface as close to the superior border as possible. The direction is parallel to the superior border. A slight tap with the mallet or firm pressure with the hand and a downward motion of the handle will uncup a portion of the roof of the apex. The remainder of the apical area is uncapped and excavated by means of specially designed curets. The posterior lip of the cavity, all of which lies internal to the internal auditory meatus can then be shaved down with a special curet. A large curved suction tube is used after the curetting is completed. This tube serves to remove the contents of the cavity and also any spicules of bone that may have been left behind. Suction is applied to the external wall of the cavity of the petrous apex so as to evacuate pus that might be retained in any of the groups of cells leading to it. The end result of this procedure is a cavity consisting of everything in the petrous portion of the bone beyond the labyrinth and the internal auditory meatus. A rubber drain is inserted and the temporal lobe is permitted to drop back into place. The wound is closed and the drain is allowed to protrude through the lower end of the wound.

**Staphylococcus Antitoxic Serum**—Dolman presents the results obtained from using antitoxic horse serum in the treatment of certain well known types of acute staphylococcal infection of human skin bone meninges and blood. The evidence reveals the probability that the severity of certain types of staphylococcal infections is due to the formation of exotoxin *in vivo* by the infecting micro organisms. An account is given of the preparation of staphylococcus antitoxic horse serum and of those of its properties which are probably of therapeutic value. Among the 104 patients there were twenty-four with various types of staphylococcal infection of the skin and subcutaneous tissues all of whom made remarkably rapid recoveries following serum therapy, thirty-two patients with severe staphylococcemia secondary to osteomyelitis in children, of whom twenty-two recovered and twenty-two apparently hope-

less cases of staphylococcemia in adults and adolescents, in five of which recovery occurred. Clinical improvement seemed to date in many serious cases from the time when the amount of circulating staphylococcus antitoxin reached a maximal high value. As the titer of circulating antitoxin rose, from absorption of the serum administered, an increasing leukocytosis was often detectable. Earlier diagnosis of staphylococcal infections and toxemias are necessary and more prompt institution of specific antitoxin therapy is important, particularly when a positive blood culture has been obtained. Although further improvements in its preparation and in methods of administration must be sought, the conclusion is reached that, when supported by adequate surgical drainage of such pyogenic foci as may be present staphylococcus antitoxic serum is a specific therapeutic agent of considerable usefulness.

**Treatment of Ringworm of the Scalp**—Davidson and his associates treated thirty-eight patients having microsporon ringworm of the scalp with thallium acetate, using the method advocated by Ingram. Thirty-six were infected by *Microsporon audouinii* and the other two by *M. felineum*. Of 170 children who either had the disease or had been exposed to it, seven showed no clinical signs of ringworm of the scalp and yet had bright green fluorescent hairs under Wood's light. This, and other tests, showed them to be infected by microsporon and probably carriers of the disease. Thallium acetate served a useful purpose in this series of cases. Of the thirty-eight patients treated, only one developed slightly toxic symptoms. Patients were always clinically cured before they ceased to show fluorescent hairs under the fluorescence lamp. It was noted during epilation that infected hairs were retained in the scalp longer than normal ones. It is suggested that this retention is purely mechanical owing to the increase in diameter of the hair surrounded by fungal spores. The authors suggest a triad for the diagnosis of the presence and absence of microsporon ringworm of the scalp: clinical examination, fluorescence test, and microscopic examination of hairs. The examination of contacts of and convalescents from, ringworm of the scalp with the fluorescence lamp should become a routine procedure.

**Mastitis Adolescentium**—Harbeson's conception of the etiology of the mastitis of adolescents is that it is caused by a disturbance in the physiologic balance between the follicular and luteal ovarian hormones. These hormones are the stimuli that cause development of the mammary gland, the follicular hormone acting on the ducts and the luteal on the acini of the gland. Theoretically a preponderance of the luteal hormone would result in overstimulation of the acini and their rapid development before the development of the ducts. There may also be a stimulation from the anterior pituitary hormone and a resulting secretion from the lobules. Since the ducts have not developed as yet, there will be engorgement and tumor formation. In a normal gland a slight secretion at puberty may occur but it is either unnoticed or may be taken care of by the lymph nodes. The author reports a case in which the condition appeared to be due to mechanical obstruction of a lactiferous duct. There were no signs of inflammation, and an infectious origin seemed doubtful. The three tumors noted were due to blocking of three separate ducts, perhaps because of underdevelopment. The condition would give rise to a moderate degree of pain and tenderness, due to tension of the secretions within the gland lobule. The course of this complaint was prolonged over some months. The diagnosis of mastitis of adolescents was made. A biopsy was thought unnecessary. The treatment in a patient with this condition is chiefly prophylactic. Cleanliness is of first importance. The breast should be protected and supported. Pain may be relieved by the application of lead and opium lotion and small amounts of salicylates. If suppuration occurs, incision and drainage are necessary.

**Blood Cytology in Experimental Syphilis I Period of Disease Activity**—Rosahn and his associates made weekly observations on the blood cytology of seven syphilitic and nine normal control rabbits. Each animal was examined seven times prior to and fifteen times after inoculation of the experimental group. Comparisons were made between the mean blood cell values obtained from all counts on the experimental and control groups in the preinoculation and postinoculation periods. The mean blood cell formula of the syphilitic group for a period of three and a half months after inoculation was significantly different from the preinoculation mean values observed in the same group in the following respects: higher total white cell, platelet, neutrophil and monocyte counts and lower lymphocyte count. The mean blood cell formula of the syphilitic group for a period of three and a half months after

inoculation was significantly different from the mean blood cell formula of the normal control group in the same interval of time in the following respects: higher total white cell count, platelet count, neutrophil and monocyte counts, and lower lymphocyte count. The authors' conclusion is that the blood cytology of rabbits infected with *Spirochaeta pallida* is characterized by an increase in the total white cell, platelet, neutrophil and monocyte counts and a decrease in the lymphocyte count from normal values. These changes were statistically significant.

**Blood Cytology in Experimental Syphilis II Period of Disease Latency**—Rosahn compared the mean blood cell levels of thirty-five latent syphilitic rabbits in which all lesions had undergone spontaneous regression and complete healing with weighted values for normal rabbits. The only differences that he noted were in the red cell count and hemoglobin content, both of which were significantly lower in the experimental group than the normal values. He observed a parallelism between the blood cell changes of the experimental disease after spontaneous regression of lesions and the cell changes in the human disease after treatment. This parallelism lends additional weight to deductions drawn from the experimental disease as applied to human syphilis.

 \*Urinary Excretion of Citric Acid I Effect of Ingestion of Large Amounts of Orange Juice and Grape Juice Cecilia Schuck, Chicago—p 679  
 \*Id II Effect of Ingestion of Citric Acid Sodium Citrate and Sodium Bicarbonate Cecilia Schuck, Chicago—p 691

**Effect of Orange Juice and Grape Juice on Urinary Excretion of Citric Acid**—Schuck reports studies made with eight women subjects on the effect of orange juice and grape juice on the urinary excretion of citric acid. The effect on urinary  $pH$ , titratable acidity and excretion of total organic acids was also observed. When 1,000 cc of orange juice or 1,000 cc of grape juice was added to a basal diet, the  $pH$  was increased and the titratable acidity was decreased. Organic acid excretion as a whole was increased. Citric acid excretion was increased. The increase produced by the orange juice was slightly greater than that produced by the grape juice, but the ratio of the amount of citric acid excreted to the amount ingested was much higher for the grape juice. With one subject, the increase represented 20 per cent more than the citric acid contained in the grape juice. The latter result indicates a metabolic source of citric acid. The increase in citric acid with the orange juice represented only from 40 to 60 per cent of the total organic acid increase. Other organic acids must have been formed in the body. From 35 to 40 per cent of the total organic acid increase with the grape juice was due to citric acid. Only a small part of this could have come from the citric acid of the grape juice and therefore most of

it can be accounted for only on the basis of having a metabolic origin. The organic acids representing products of metabolism may arise as a result of the alkalizing effect of the fruit juices.

**Effect of Citric Acid and Sodium Bicarbonate on Urinary Excretion of Citric Acid.**—In a study made with six women subjects given citric acid, sodium citrate and sodium bicarbonate, Schuck observed that the citric acid produced little or no change in the  $pH$  of the urine, but that the sodium citrate brought about a marked increase. The titratable acidity was slightly decreased as a result of the ingestion of citric acid, while the sodium citrate brought about a marked decrease. Total organic acid excretion was decreased by the citric acid but greatly increased by the sodium citrate. Citric acid excretion was decreased in some cases and increased in others as a result of the citric acid ingestion, while the sodium citrate brought about a marked increase in every case. The results are in agreement with those obtained by Östberg. The total organic acids and citric acid excreted as a result of the ingestion of sodium citrate amounted from two to three times the excretion on the basal diet. The increase in  $pH$  and the decrease in titratable acidity brought about when sodium bicarbonate was fed were accompanied by a small increase in total organic acids and a considerable increase in citric acid excretion. Apparently, citric acid excretion is not dependent on citric acid ingestion. The author believes that citric acid is one of the organic acids which play a part in acid base balance regulation.

**Hemochromatosis and Metabolism of Iron and Copper.**—Dry tries to show that hemochromatosis is a definite clinical as well as pathologic entity and that the mechanism underlying the cirrhotic and pigmentary changes as well as the diabetic syndrome of hemochromatosis is not explicable on the basis of that which ordinarily leads to these conditions when they occur as separate diseases. The multiplicity of hypotheses as to the etiology of hemochromatosis, as found in a review of the literature, reveals the incompleteness of knowledge of the disease. The evidence is insufficient to establish copper

as the cause of hemochromatosis, although it may conceivably cause hepatic cirrhosis under certain conditions. It has been shown that its presence in the body, especially in the liver, is not conclusive evidence that it is a factor in the cause of the disease. There is no evidence to show that the excess of iron in hemochromatosis is the result of excessive hemolysis or that retained food iron is itself the cause of the disease, since it occurs without the accompanying pathologic characteristics of bronze diabetes. The author presents the study of a case of hemochromatosis, together with its iron balance with an evaluation of the results of such studies, and considers certain aspects of the normal metabolism of iron in relation to its possible perversion in hemochromatosis. He believes that hemochromatosis is due to faulty elimination of iron and not to simple retention of food or hemoglobin iron. There is an inborn error of metabolism, expressing itself as a disturbed intracellular circulation of iron leading to injury and death of the cell and its replacement by fibrous tissue.

**Coronary Disease, with Reference to Acute Conditions of the Abdomen.**—In studying a series of 141 cases, Morrison found two cases in which a diagnosis of cholelithiasis was made roentgenologically. The gallbladder was removed and later the patient returned with a recurrent attack of pain and a typical electrocardiographic tracing of coronary disease. A chart is presented in which pain, in the entire series, is graphically shown, from which it is seen that almost 13 per cent of coronary cases show epigastric pain only, and if seen early are apt to present a problem in diagnosis. One can easily be placed in the embarrassing position of waiting for the heart to show some signs of injury and in the meantime allow some serious acute abdominal condition to wait too long. The reverse may be quite as disastrous. The heart should always be carefully investigated in any suspected lesion in the upper part of the abdomen.

**Median Nerve Palsy Produced by Intravenous Injections**—Stevens reports three cases in which the median nerve has been injured as the result of intravenous injections of calcium chloride when the median basilic vein was utilized. Either because the aperture of the needle is not completely within the lumen of the vein when the injection is made or because of a leak from the puncture in a sclerotic vessel, some of the solution escapes into the surrounding tissues. The amount may be insufficient to show any local swelling but pain is felt locally during the operation and in the distribution of the median nerve or the median cutaneous nerve of the forearm. Zutt believes that the effect of the calcium solution is not produced by any contact of the needle with the nerve but is due to a spread of the solution (with its precipitant action on tissue proteins) from the site of puncture.

Attempted Cultivation of Vaccinia Virus in Conjunction with Non-pathogenic Micro-organisms C R Amies—p 185

**Infection by Vibrio Septique from the Alimentary Tract**—Borthwick states that hydrogen ion concentrations from pH 5 to 6 are most favorable for the maintenance of activity of Vibrio septique toxin. The hydrogen ion concentration of the gastric contents is of little importance in determining the production of a Vibrio septique infection from the alimentary canal. Animals in which alimentary activity has been reduced by the drug narcotine frequently show evidence of infection by Vibrio septique after intragastric administration of culture. The exposure of guinea-pigs to a low temperature before the administration of culture, predisposes to infection by Vibrio septique. Culture at approximately 0 C, introduced into the stomach of normal animals, does not readily cause infection. The general character of the changes found in the internal organs on postmortem examination indicates the presence of a toxemic condition in animals infected by Vibrio septique. The intragastric administration of toxin alone to guinea-pigs, whether normal, with the gastric contents adjusted to pH 5 or 7.6, or treated with narcotine, does not produce intoxication. The toxin is apparently not absorbed from the lumen of the stomach.

**Influence of Temperature on Vaccinia Virus**—The experiments of Amies demonstrate that pure vaccinia virus suspended in a simple broth medium can withstand a temperature of 37 C for several weeks, while at room temperature the potency remains at a high level for a considerable period. No attempt was made to obtain by selection a heat-resistant strain

of virus. It seems more likely that the capacity to withstand heat depends entirely on the initial virulence of the strain employed. Whether individual elementary bodies may increase their virulence or whether it is only a question of the number of elementary bodies present it is as yet impossible to say. The possibility of employing pure suspensions of vaccinia elementary bodies for jennervian prophylaxis has been under consideration for some time. The observations regarding the heat resistance of these bodies, and their viability when maintained at 0 C, strengthens the belief that these bacteria free suspensions may be found of value in the practice of vaccination.

**Treatment of Acute Infective Arthritis of Knee**—Mount suggests the injection of from 2 to 3 cc of ether into the knee joint in the treatment of punctured wounds about the knee when there is doubt as to whether or not the joint cavity has been penetrated. When the wound has involved the joint the ether blows out from the external orifice, and immediate excision of the whole wound tract is indicated. The reaction set up by the ether in the synovial membrane appears to stimulate its resistance to infection. Immobilization with suspension of the limb and weight extension and, if need be, repeated aspirations of the joint exudate are carried out. When, however, acute infective arthritis of the joint develops or is already established when the patient comes under observation, further steps on the lines of the Kanavel treatment of infections spreading up the forearm from pyogenic infection of the common flexor sheath are recommended. The author reports four cases in which such treatment has been successful.

A Comparison of the Results Obtained with Three Different Methods of Induction of Labor at Guy's Hospital Between 1928 and 1932 L H deB Crowther Smith—p 250

**Functions of Epithelium of Gallbladder**—According to Harding, the mucosa of the gallbladder has functions both of absorption and of secretion. Since only one type of epithelial cell is present, it follows that one and the same cell can, and does, pass materials in two opposite directions. This is a

physiologic state to which attention has not been drawn before. The epithelial cells of the gallbladder mucosa both secrete into the lumen of the organ and absorb from that lumen. It is doubtful whether it can be shown that any other simple epithelium functions similarly in two opposite directions, although it may be the case in the intestine.

**Eosinophilia in Allergic Conditions**—Knott and Pearson endeavor to confirm or disprove the observations of Kline and his co-workers whether a clinical method might be developed for determining whether a patient is allergic or nonallergic by examining the mixture of wheal fluid and blood obtained by pricking the site of a histamine wheal. The authors found that the eosinophil concentration is doubled in the wheals produced by injecting appropriate proteins into sensitized patients and that the injection of proteins to which they were not sensitive into the same persons produces no eosinophil concentration. At the site of histamine wheals there is eosinophil concentration in both sensitized and nonsensitized persons, the actual number of eosinophil cells seen in the films from the wheal varying directly with the number in the circulating blood. Compared with the blood film in nonsensitized subjects the film from the histamine wheal shows on an average approximately twice as many eosinophil cells. In sensitized patients the average increase is higher from two and a half to three times. The study suggests that the occurrence of eosinophil concentration depends on the type of reaction produced in the skin. Only in actual histamine wheals or in skin reactions showing the typical triple response described by Lewis does any marked eosinophil concentration occur. Examination of films prepared as described from lesions of this type by magnifying it, certainly calls attention to any tendency to blood eosinophilia. The test appears to call attention to the class of person that has been termed a latent allergic patient. Although it is true that some eosinophil concentration occurs in the histamine wheals produced in normal controls the authors' data show it to be more marked in those presenting allergic tendencies.

**Respiration in Psychotic Subjects**—Paterson examined sixty-two normal subjects and 121 schizophrenic patients as to the depth and rate of their respiration by means of a plethysmographic apparatus. The schizophrenic patients were found to breathe more shallowly and more rapidly than the normal subjects, the difference being significant. This difference did not apply to twenty-five melancholic patients. It was pointed out that the type of respiration employed by the schizophrenic patient was an inefficient one. The author discusses the significance of this different type in relation to oxygen consumption, and to its possible bearing on the catatonic state with its stupor and cyanosed extremities, also in connection with the relation of the schizophrenic patient to tuberculosis, and to the dozing and sleeping states.

**Liquid Petrolatum as Cause of Loss in Weight**—Till points out that, as liquid petrolatum is not absorbed to any extent by the stomach and intestine, it seems natural that the oil when given daily in fairly large doses and for a considerable period of time will coat the mucous membranes of the stomach and intestine and so prevent the digestion and absorption of food with a consequent loss of nourishment to the body, thereby causing a loss in body weight. When the use of this laxative is discontinued the oil coating the mucous membranes of the digestive tract is gradually eliminated by the natural channels, the stomach and intestine fulfil their normal functions, and the body again receives sufficient nourishment, which is shown by a gain in weight. The author presents cases that appear to agree with this theory.

**Hypoglycemia and Ketosis Their Relation to Antral Disease and Bronchiectasis**—Sippe presents evidence in support of the view that hypoglycemia and ketosis are important pointers to the etiology of some cases of chronic sinusitis and nontuberculous pulmonary fibrosis. This underlying pathologic change is probably a chronic hydration of the protein particles of the blood. He reports three early cases with complete relief of symptoms and signs, and six advanced cases. Many of the persons who develop chronic sinusitis and pulmonary fibrosis have an exudative diathesis as the basis for the development of the lesions in the respiratory tract. Frequently this inability to retain water in the tissues is due to an insufficient supply of available dextrose, as evidenced by hypoglycemia or ketosis. The author performed the blood sugar estimations by the micromethod of Hagedorn and Jensen. Rothera's test was used in the detection of acetone, and the percentages were compared with standards prepared by dilution of acetone in urine. Percentages of 0.016 and higher all gave the strongest positive reaction.

**Duration of Ventricular Systole**—Lian and his co-workers studied the electrocardiograms of a large number of normal persons at rest and after effort. The respective duration of the systole and the diastole was thus measured in relation to a frequency of normal cardiac contractions varying from 63 to 133 pulsations per minute. They were then able to express the systole-diastole relation in the following formula  $K = \frac{D}{C(C-41)}$ , in which  $D$  was the duration of the diastole expressed in hundredths of a second and  $C$  the entire cardiac cycle expressed similarly. The normal physiologic value of  $K$  was found to vary between 0.0040 and 0.0049. The duration of the systole is increased if  $K$  has a value below 0.0040 and is decreased if  $K$  is above 0.0049. The relative lengthening of the ventricular systole in hypertensive persons constitutes a sign of functional overburdening of the ventricular myocardium. In about two thirds of these cases this sign is added to the manifest evidence of cardiac insufficiency and constitutes a diagnostic confirmation. In one third of the cases it may be the forerunner of clinical signs of cardiac insufficiency. It is noteworthy, however, that cardiac insufficiency may exist without modifying the normal relations of systole and diastole. In primary myocardial insufficiency the lengthening of the ventricular systole is of a frequency in harmony with the degree of cardiac insufficiency. In valvular cardiopathies there are some rare cases of relative shortening of the ventricular systole. This occurs especially in mitral stenosis. In exceptional cases this is seen in cardiac insufficiency. The authors conclude that the formula given makes it easy to determine the lengthening and the shortening of the ventricular systole on the electrocardiogram, and their presence permits interesting clinical deductions.

**Bloody Discharges from Nipple**—Bloch and Wechsler describe two cases in which a persistent bloody discharge from the nipple had existed for many years. Operative intervention in both instances revealed papillomatous lesions of the galactophorous canals. The lesions appeared as black milium cysts disseminated in the subareolar portion of the gland. These small cysts occupied an absolutely central zone and did not extend beyond a radius of 2 cm. They extended about 3 cm in the depth of the gland. The technic of operation involves general anesthesia and a semicircular incision at the edge of the areola of the nipple. The gland is separated from the skin, and the galactophorous canals at the base of the nipple are resected. Drainage at the lower border of the areola of the nipple is maintained for forty-eight hours. The scar is invisible and the shape of the breast is little altered. In the rare instances when neoplastic lesions are found, radical amputation is the only logical operation.

**Gastrotherapy in Pernicious Anemia**—For their recent studies, Etienne and his co-workers used an extract of the gastric mucosa of the hog in powder form. This product was always taken in moderately warm meat bouillon at the beginning of a meal containing a dish of meat. The doses were from 30 to 40 Gm., depending on the intensity of the erythrocyte deficiency and representing about 200 or 300 Gm. of fresh mucosa. In general the powder was acceptable enough to the

patients in spite of its slightly repellent odor. Only two of the authors' eleven cases are reported in detail. In the first case liver extract had initiated an anchioration, which was reinforced to complete erythrocyte reformation by the stomach extract. The activity of the extract was undeniable since, after the patient went home, continued administration of the preparation caused the erythrocytes eventually to exceed 8,000,000 per cubic millimeter. Gastric analysis failed to show any return of the natural antipernicious principle. The second case involved a grave plastic pernicious anemia with neurologic signs but without hemorrhagic manifestations. In this case the neurotropic and anemic syndrome improved at the same time. In six other cases the results were likewise good. In two with the hemorrhagic form of pernicious anemia, administration of the extract failed to modify the fatal outcome. They conclude that the therapeutic action of the extract is incontestable and is more precise and constant than that of liver extract. The action by mouth is also real. The therapeutic action manifested itself in seven of nine of the cases of plastic or aplastic pernicious anemia without the hemorrhagic syndrome. Gastric extract acts especially on hematopoiesis. Achylia persists in spite of functional and erythrocyte improvement. A certain degree of mononucleosis persists even after the erythrocytes return to normal.

\*Study of Hydrolability in Early Infancy S. E. Burgh—p. 75

\*Early Diagnosis of Measles Sign of Semilunar Fold and Prodromal Measles Angina R. Meyer—p. 85

**Hydrolability in Early Infancy**—Burgh discusses the group of children whose defective organic constitution or dis-equilibrium is clinically manifested by great oscillations in weight. In these children examination of the metabolism reveals an instability in the degree of hydration and mineralization. There is some normal or physiologic hydrolability in the first three months of life, and only that which persists after the first three months must be considered pathologic. The first striking fact was the frequency of hydrolability in the infants admitted to the hospital service as compared with those seen in private practice. This led to the thought that constitutional factors are less important than exogenous ones, such as inadequate alimentation, hygienic mistakes and infections. It was remarked that 90 per cent of the nurlings who entered the hospital service were dystrophic and the majority seriously dystrophic. These children become dystrophic because of previous hydrolability, but the author attempts to show, on the contrary, that they are hydrolabile because they are dystrophic. It was possible to show that certain infections, particularly latent otitis and diphtheritic rhinitis, digestive disorders, prolonged qualitative and quantitative hypo-alimentation and certain intoxications of acidotic type may so profoundly alter the histologic structure and functional capacity of the tissue cells that they become unfit to fix water. In this manner the state of wasting is produced which Finkelstein mentions under the name of decomposition. These different factors not only produce the loss of water from the tissues of hydrolabile children but also change the mechanism of water metabolism. It is certain that such effects are produced more easily in physiologic or constitutional hydrolabile children, but they are also observed in simple dystrophies, which become hydrolabile under the action of the same causes.

**Early Diagnosis of Measles**—Meyer calls attention to a preeruptive sign of measles originally described by his father. It precedes Koplik's spots and consists essentially in a turbescence with intense reddening of the semilunar folds of the eyes. It is seen in no other infectious disease. Conjunctivitis may be confusing at first, but the pronounced contrast between the redness of the fold and that of the palpebral conjunctiva and caruncle does not exist in other types of conjunctivitis.

The sign varies in frequency in different epidemics. Recently the author has been able to demonstrate it in three cases out of twenty, which allowed the diagnosis to be made before the eruption. Sometimes this sign seems to alternate with that of Koplik. Thus in the same epidemic a certain percentage of the children show the "semilunar" sign, others the Koplik sign, or more rarely the "semilunar" precedes the Koplik sign, or both may be entirely missing. It is curious that the "semilunar" sign diminishes when the others appear. Ordinarily it is during the first or second day of the fever that this sign appears. The author believes that this sign is important when one admits that measles is contagious only in the preeruptive stage.

- Hypersensitivity to Iodine and Occult Sources of Iodine. F Blum—p 560

**Differences in Sensitivity in Abdominal Symptoms**—Voegeli determined the relations between symptomatology and individual susceptibility to pain. He employed Libman's test in which the thumb is pressed against the tip of the mastoid bone and then forward against the styloid process. Five years' experience with this test revealed that abdominal disturbances have a normal symptomatology only in sensitive patients while hyposensitive persons show rudimentary symptoms or none at all. The determination of the sensitivity is therefore highly important for the evaluation of symptoms, and it also aids in differentiating organic from neurotic signs. The author admits that there are many different degrees of sensitivity, but he maintains that for diagnostic purposes the classification of sensitive and hyposensitive is adequate because the hypersensitive person reacts in the same manner as does the normally sensitive person. He related the clinical histories of several patients, in whom the test revealed hyposensitivity and in whom only roentgenoscopy disclosed grave internal disorders, such as calculi and ulcers.

**Lambliasis During Childhood**—Gross considers it surprising that in spite of the frequent stool examinations, which are made for the detection of helminthiasis, *Lambia intestinalis* is so rarely detected. The author is unable to state the role of the World War and the presence of foreign troops in Europe in the dissemination of this originally tropical disorder. Lambliasis is now found in all social groups in persons who have never left their home district. Galli-Valerio, who first called attention to lambliasis in Europe maintains that it is transmitted from man to man but considers it also likely that rats and mice are sources of infection. The general symptoms of lambliasis are weakness, lack of appetite, undernourishment, headaches and pallor of skin and of mucous membranes in spite of a normal hemoglobin content. Other symptoms are dependent on the localization of the parasites. There may be spasmodic or dull abdominal pains and intermittent diarrhea. Children with lambliasis frequently soil their bedclothes and underwear. The symptoms are characterized by a certain periodicity. The author stresses the absence of leukocytosis and the fact that deviation to the left is barely indicated. In one instance he observed eosinophilia. He describes the examination of the feces and points out that during the time when cysts are not eliminated the differentiation from tuberculosis may be difficult. Various chemicals (cimetidine, methylthiourea chloride, quinine acriflavine hydrochloride and so on) have been tried in the treatment of lambliasis but most authorities now agree that the arsenic compounds, particularly acetarsone, give the best results. The latter is given by mouth in the form of tablets, each containing 0.25 Gm of acetarsone. The dosage is gradually increased. For several days the child is given one tablet and then for several days two tablets. After a pause of four days, three tablets are given daily for about

ten days, and after another pause of four days, four tablets are given daily. In another case as high as six tablets were given daily.

**Ketonic Curve After Ingestion of Sugar as Test of Hepatic Function**—De Flora studied twenty-one patients, sixteen of whom had hepatic ailments, eight a normal liver and three diabetes. The ketonemia was determined after all patients had fasted for twenty-one hours. The author found that the ketonemia is higher in hepatic patients than in normal subjects, although in some cases the opposite occurred. This, combined with the fact that some hepatopathic patients showed a diminishing ketonemia with the aggravation of the disease, takes away much from the symptomatologic security of the dosage of sugar on a fasting stomach. The ketone bodies in persons with a normal liver increase after ingestion of sugar either in single fractions or in their entirety, after from thirty minutes to one hour and sometimes also two hours, after which lapse of time they diminish. Such an increase is most notable, rising to double or even triple the initial rate. The ketone bodies diminish after ingestion of sugar in hypohepatic patients, this diminution involves all fractions to the point of attaining at times less than half of the ketonemia on a fasting stomach. The rate of ketonemia after ingestion of sugar runs parallel to the condition of the hepatic function, good hepatic function is accompanied by high rates of ketonemia and vice versa. Such behavior is constant in the case history and is always in accord with the amino acidemic curve and also with the clinical symptomatology. The author considers this ketonic curve after ingestion of sugar a test of hepatic function. It also shows the specific function of the liver in carbohydrate metabolism and ketogenesis.

- Congenital Myxedema. Therapy by Synthetic Thyroxine. D Diehl and J C Pellerano—p 803

**Treatment of Hemoptysis by Intratracheal Injections of Hemostatics**—In the treatment of grave hemoptysis, especially of tuberculous origin, Vaccarezza reports satisfactory results from intratracheal injections of hemostatics, with the following technique. After anesthetization of the palatopharyngeal region of the patient by means of a spray with a 5 per thousand solution of nupercaine, the patient is placed in the abdominal decubitus and instructed to put his tongue out forcibly. Then with a syringe provided with a bent cannula the hemostatic solution (10 cc of coagulen or of thromboplastin, to which 0.001 Gm of epinephrine has been added) is slowly instilled at the middle of the base of the tongue so that it goes to the pharyngeal vestibule and then to the tracheobronchial tree. When the hemorrhage comes directly from the lung the patient is instructed to take a certain position in which the penetration of the solution into the lung is secured since the hemostatic action of the solution is more energetic when it is allowed to be in direct contact with the bleeding focus. To prevent the expulsion of the solution in patients with a marked cough reflex, it is advisable to give an injection of morphine or to instillate a few cubic centimeters of a 1 per cent solution of procaine hydrochloride if there are no contraindications to the administration of opiates. Hemostatic injections may be repeated every twelve, twenty-four or forty-eight hours, according to the indications of the given case and to the effects obtained. Sometimes the hemorrhage dis-

appears with a single injection, in other cases it is gradually attenuated and completely disappears in a few days. In rare cases the treatment fails. The author considers the method valuable because of its simple technique, its action to check or greatly diminish the hemorrhages and the absence of any possible complications and accidents, such as those sometimes observed after the intravenous administration of coagulum.

**Diagnosis of Roentgen Micronodular Images of Lung**—Dutrey states that the roentgen micronodular images of the tuberculous lung may be due to certain forms of fibrous tuberculosis or be caused by bronchial aspiration of blood during hemoptysis, without having in any case any relation to miliary tuberculosis. The intrapulmonary localization of blood after hemoptysis follows, as a rule, a benign evolution but some fatal cases may occur. There are cases in which the post-hemoptytic micronodular shadows instead of being reabsorbed in a few months, remain, definitely giving the impression of having been transformed into a chronic miliary tuberculosis of bronchogenic origin. The existence of chronic miliary tuberculosis cannot be denied since the presence of the disease has been proved in some necropsies. Chronic miliary tuberculosis, Benzançon nodular fibrous tuberculosis and the intrapulmonary bronchogenic repletion of hemoptytic blood have similar clinical and roentgen characteristics, which make a differential diagnosis difficult. There are many nontuberculous pulmonary diseases, such as influenza, syphilis, tumors, pneumonococcosis, miliary bronchopneumonia and cardiac diseases, capable of producing roentgen micronodular shadows of the lung so similar to those given by miliary tuberculosis that it is nearly impossible to make an exact differential diagnosis by the simple roentgen examination of the lung. Confusion arises even when the two anatomic parts are held and observed together. Writers who describe cases of this nature have noted that the shadows attributed to miliary tuberculosis which followed a favorable evolution probably were produced by the nontuberculous diseases. The author believes that, since the micronodule is the fundamental lesion which appears in the roentgenograms of all the aforementioned tuberculous and nontuberculous diseases, the term "granula" should be replaced by the term "micronodula," which includes all pulmonary micronodules of both tuberculous and nontuberculous etiology, and also because the new term would not suggest any etiologic or anatomic concept as does the word "granula."

\*Surgery of Facial Furuncle. W. Schmid—p. 447.

**Surgery of Facial Furuncle**—Schmid reports eighty-one cases of facial furuncle treated conservatively. The mortality rate in this group was 10 per cent. The conservative method consists of absolute rest in bed. The patient is not allowed to speak and is fed a fluid diet through a tube to avoid the act of chewing. Vaccines, antitoxins, nonspecific proteins and bactericidal drugs have not proved to be of any value. The author was impressed with the beneficial effect of the administration of insulin to nondiabetic patients in doses of from 10 to 20 units daily in cases of severe suppuration. For local applications he used the gray ointment in combination with ultraviolet rays. He is opposed to hyperemia treatment because it makes it difficult to observe the progress of infection. Injection of blood about the lesion, according to the method of Laven, leads to further tissue damage and does not seem to influence the progress of a malignant furuncle. The author's later experiences led him to believe that some of the fatalities in his series could have been prevented by timely radical intervention. He therefore advocates conservative treatment for mild infections (benign furuncles) and radical treatment for grave (malignant) furuncle or carbuncle of the face or the occiput. The symptoms of a malignant infection are progressing edema spreading infiltration, thrombophlebitis, fever, fast

pulse, severe pain, chills and a positive blood culture. The author advocates a wide total excision of the lesion with a diathermy knife for such cases. The wound is loosely covered with iodoform gauze and is not disturbed for ten or twelve days. After this period the wound is dressed every fourth or sixth day. The resulting scars are surprisingly small and require corrective plastic operations in a small percentage of cases.

Cr. Gangrene with Recovery. Wullenweber—p. 901.  
Spinal for Persons Suffering from Writers' Cramp. Gontermann—p. 902.

**Test for Diagnosis of Lead Poisoning**—Behrens describes how lead passes through the organism, what organs store it and what is the chemical foundation of the behavior of lead in the organism. In experiments on mice he observed the passage of lead through the gastro intestinal tract. He found that the resorption of the ingested lead is slight during the first few hours but then increases gradually. After eight hours 6 per cent, and after twenty hours about 10 per cent of the ingested lead is demonstrable in the body. Then the lead content decreases again, but even after sixty hours from 3 to 4 per cent still remains. Tests on the excreta of mice revealed that the largest portion of the lead passes through the intestine without resorption. This observation is important for the detection of deception in rendering decisions in matters of compensation, because the presence of large quantities of lead in the feces indicates that it was newly taken in and not that the organism eliminated stored lead. The resorption of the lead is dependent not only on the solubility of the administered compound but also on the nature of the other intestinal contents. For instance, the simultaneous administration of milk results in a poorer resorption of lead. The author describes blood tests on the resorption of lead which revealed that by far the largest portion is bound to the erythrocytes and that the plasma contains a comparatively small quantity. Injection of a lead compound into pregnant rats showed that the lead is primarily absorbed by the bones, the liver, the kidney and the intestine of the fetuses. The lead seems to be deposited primarily in those portions of the bones in which the mobilizable calcium depots are assumed to be. The author gained the impression that as regards resorption, storage and elimination, lead has a certain similarity to calcium. The fact that the phosphates of calcium as well as of lead are the compounds that dissolve with the greatest difficulty under the conditions that obtain in the organism may be taken as the chemical explanation of this similarity. That lead deposits may still be present in the bones years after a lead poisoning is also readily understandable on the basis of these observations. The author considers unsatisfactory most of the methods of analysis by which the presence of lead is demonstrated and suggests that they should be replaced by one that is based on the fact that diphenylthiocarbazon forms with lead complex stained compounds.

Hemolytic Anemia with Nocturnal Hemoglobinuria. K. Jglauer and S. Frenkel—p. 880.

**Differentiation of Closely Related Micro-Organisms**—Jadassohn and his associates point out that, because of the great significance that Brucella abortus infection has assumed

in recent years, its relation to *Brucella melitensis* as well as to infections with other forms of *Brucella* has become of greater interest. Various methods have been tried in the differentiation of the different types of *Brucella*, but the difficulties that are encountered are still considerable. The authors decided to resort to the method of Schultz-Dale (anaphylaxis experiments on the surviving uterus of guinea-pigs), although up to now this method had never been used for this purpose. Past experiences on the specificity of this reaction against various antigens gave promise of success. For the preparation of the antigens the authors resorted to a method in which the C factor becomes concentrated and they designate the filtrates thus obtained "dry brucellins." They found that the use of dry brucellins in the Schultz Dale test makes it possible to produce specific reactions. The specificity is sufficient to prevent cross reactions between human, cattle, melitensis and swine strains.

**Hemolytic Anemia with Nocturnal Hemoglobinuria**—Iglauer and Frenreisz relate the history of a man aged 42, who, in the course of four years gradually developed hyperchromic anemia with hemolytic icterus and nocturnal hemoglobinuria. The latter recurred every twenty-four hours. With the blood picture, the case could be differentiated from familial hemolytic icterus. The condition could not be classified with the paroxysmal hemoglobinurias. It was impossible to clarify the etiology of the disease and it proved likewise impossible to reduce the hemolysis. The authors assume that the hemolysis was probably caused by changes in the erythrocytes. The hemoglobinuria was, as regards time, closely connected with the fluctuations in the hemolysis and could not be explained on the basis of the hemolytic properties of the blood serum.

\*Demonstration of Ureteral Calculi That Do Not Produce Shadows E. Pflaumer—p. 910

Action of Acetylcholine in Scleroderma H. Rittenbruch—p. 911

**Treatment of Stiffening of Fingers and Hand**—Lange shows that by suitable, early treatment the stiffening of the fingers usually can be overcome. The reestablishment of motility deserves especial attention, when stiffness of the fingers develops as the result of prolonged immobilization or scar traction in injuries of the arm. These secondary forms are usually more amenable to treatment than those that are the direct result of an injury or of an extensive suppuration. The best treatment of the secondary forms is prophylaxis. Fracture of the radius is the injury most often followed by stiffness of the fingers. This is caused by the fact that the fingers are unnecessarily included in the bandage completely or at least partially and the author emphasizes the necessity of leaving the fingers sufficient freedom so that complete closure of the fist is possible. The second important factor is that the fingers should be used again as early as possible and the author points out that the bandage prescribed by Bohler for the fracture of the radius makes this possible. What applies to the radius applies also to other injuries of the arm. The treatment of stiffness necessitates exercises. The manual passive finger movements that are performed by the physician or the masseur are not advisable for they frequently aggravate instead of improving the condition. The movement exercises must be conducted in such a manner as to avoid pain and by the effect of a force acting for a longer period to overcome gradually and exclude the tension of the musculature. This can be accomplished by a device that employs elastic adhesive tape or by a special strap bandage both of which are described and illustrated. In more severe cases weight traction becomes necessary. As soon as improvement has been obtained by passive movements active movement exercises are instituted. In cases in which a partial muscular paralysis is responsible

for the contracture of the hand or the fingers, the treatment is more difficult. It has to be determined for each individual case how the existing muscular power can best be utilized to achieve the best possible motility of the hand. Less important movements may have to be dispensed with in order to make more important ones more effective. For instance, for the use of the hand the movement in the wrist joint is less important than the capacity to bend and stretch the fingers and particularly the movements of the thumb. Thus an operative stiffness of the wrist joint may be resorted to in order to utilize the available muscle power for the flexors and extensors of the fingers.

#### Ramstedt's Operation in Pylorostenosis of Nurslings

—On the basis of observations on 102 nurslings with pylorostenosis on whom he himself performed Ramstedt's operation, and of reports from the literature, von Haberer shows that the intervention which consists in a transverse incision through the thickened serosa and muscularis down to but not through, the mucosa, produces excellent results and that the operative mortality is low (from 2 to 35 per cent). Whenever high mortality rates are reported, they are largely the result of a belated operation that is, irreparable disturbances of the metabolism or of the stomach had already developed before the operation was resorted to. The author admits that the surgeon cannot expect every nursling with pylorospasm to be referred to him for operation. He thinks, however, that by close cooperation between the pediatrician and surgeon the results of the conservative as well as of the surgical treatment can be improved.

**Demonstration of Ureteral Calculi not Producing Shadows**—In a former report, Pflaumer showed that about 20 per cent of urinary calculi do not produce shadows in simple roentgenoscopy. Here he gives the history of a man, aged 27 in whom the ordinary roentgenogram did not reveal a calculus. Several other roentgenologic methods were employed and a calculus was finally discovered when a roentgenogram was made in the semilateral position. A pistachio-shaped calculus was detected in the oxygen-filled sacral portion of the ureter. Projection away from the vertebral column has given such satisfactory results ever since then that the author now regularly uses the semilateral position whenever a calculus is suspected in the ureter. Since this exposure is, however, not suitable for the renal pelvis, the buttock of the contralateral side is lifted slightly, but not the shoulder, thus the ureteral shadow does not fall together with that of the vertebral column, while the renal pelvis is demonstrated in the frontal plane.

Posterior Occipital Presentation K. Holzapfel—p. 1342

Intra Uterine Death of Fetus Caused by Rupture of Placenta R. Volbracht—p. 1350

**Torsion of Pedicle of Ovarian Tumors**—Monch, after calling attention to the fact that Küstner's law of the torsion of the pedicle of ovarian tumors is often misunderstood points out that the impulses from the intestine are directed forward and outward and that consequently the tumor is turned outward. This would also prove Thorn's theory that Küstner's law applies only to those tumors that are located on the side on which they originated. If, however, the tumor is on the opposite side, the torsion would again be outward but would be opposed to Küstner's view according to which the pedicle of the ovarian tumors of the right side undergo a left spiral turn and those of the left side a right spiral turn. Not only Thorn but also Cario and Mann assume that all tumors are turned outward. But while Thorn finds the cause of this regularity in the structure of the pelvis and of the abdomen, others consider the growth of the tumor the determining factor of a regular or irregular torsion. Monch experimented with a box, a rubber ball fastened on a band (representing the pedicled tumor) and boiled spaghetti (taking the place of the intestine) and reached

the conclusion that Thorn's opinion is correct, that every ovarian tumor, provided unusual conditions do not prevent it, is turned outward. The torsion takes place especially in case of flaccid abdominal walls. Küstner's law is valid in tumors that lie on the side of their origin. The author admits that, outside of the movements of the intestine many other factors may lead to torsion of the pedicle of ovarian tumors.

\*Morphologic Alterations of Blood in Acute Rheumatism V. V. Pezharskaya — p 771

\*New Method of Determining Bilirubin in Blood Serum V. I. Kazakov — p 804

**Serum Therapy of Botulism**—According to Velikanov, botulism is more frequently an intoxication with the toxin of *Bacillus botulinus* than an infection with the bacillus itself. This toxin has selective action. It affects the motor nerves, while the sensory nerves are never involved. The incubation period in the author's series varied for periods of from one hour to as late as ten days in one case. The latter suggests the possibility of the development of the specific germ in the gastro-intestinal tract. The first symptoms may be those of acute gastro-enteritis. These, however, rapidly subside to be followed by symptoms of involvement of the motor nerves. The following may be observed: ptosis of the upper lid, mydriasis and rigid pupils, diplopia, impaired vision because of loss of accommodation, aphonia, difficulty in deglutition, dry mouth, and weakness of the muscles of the abdomen, the neck and the jaws and of muscles of respiration. The temperature is subnormal. The pulse is slow in the beginning, but later becomes accelerated. There are headache, noises in the ears and pronounced general weakness. Death is due to respiratory or cardiac paralysis. Consciousness remains clear. The mortality, as reported from various countries, amounts to from 52 to 67 per cent. The author prepared a specific serum from horses against the three types (A, B, C) of *Bacillus botulinus*. He states that in a group of 114 patients treated with the serum the mortality rate was 20 per cent, while in 75 patients not so treated the mortality rate amounted to 93 per cent. He concludes that the serum is the only effective means of treating botulism. The effectiveness of the serum depends on its early administration. Delayed administration of serum in rapidly progressing intoxication may still be made effective if given in large doses, preferably by the intraspinal route.

**Alterations of Blood in Acute Rheumatism**—Pezharskaya reports the morphologic alterations of the blood in 420 cases of acute rheumatism. The morphologic picture and the leukocytic formula were studied in 300 of the cases, and the morphologic picture, leukocytic formula and sedimentation reaction of the erythrocytes in 100. Anemia of a mildly hypochromatic type was observed in the early stages of uncomplicated cases. A more pronounced anemia was observed in recurrences, in exacerbations of the endocarditis, and in the complications of the original process. Leukocytosis present in the early stages (from 10,000 to 15,000) is not indicative of the gravity of the disease. After the thirtieth day from the onset a leukocyte count above 8,000 was observed only in exacerbations or complications of the traumatic process. A rise of the leukocytes corresponds to a rise of the temperature in the acute stage and precedes the rise in temperature due to a complication or an exacerbation. In the early stage the leukocytic formula shows a shift to the left. In cases in which there is manifest involvement of the heart, especially myocarditis and pericarditis, as well as in the presence of complications, there was observed a relative neutrophilia and a lymphocytopenia. There is a diminution of eosinophils in the acute stage. In

cases of myocarditis and endocarditis or in severe recurrence there may be an eosinophilia and, occasionally, a mild monocytosis. During convalescence, the relative lymphocytopenia was replaced in 50 per cent of the cases by a relative lymphocytosis. In some cases a mild eosinophilia was noted. The author failed to establish either a constant or a definite relationship between the hemoglobin values and the sedimentation reaction of the erythrocytes. She concludes that the blood picture in acute rheumatism reveals nothing of the nature of the disease. The blood picture reflects a weak cellular reaction on the part of the hematopoietic system to the pathologic process present. A pronounced anemia in the beginning of the acute stage suggests the coexistence of another process or of a complication. High leukocytosis in the incipient stage with marked joint symptoms suggests either the existence of a complication or a joint infection of other than rheumatic nature, possibly of gonorrheal etiology. The sedimentation reaction of the erythrocytes is a more sensitive indicator of an approaching exacerbation or complication than the leukocytosis.

**Method of Determining Bilirubin in Blood Serum**—The disadvantages of the van den Bergh test, according to Kazakov, are the necessity for a special colorimeter and the not infrequent lack of correspondence between the shades of the tested solution and those of the standard, as well as the loss of a portion of the bilirubin through absorption by albumin in the field of reaction. In a method proposed by the author, the qualitative determination is made by the addition of a 20 per cent solution of trichloroacetic acid after the method of Vogl and Zins. The quantitative determination is made after Herzfeld's modification of the van den Bergh test. The method is recommended because of its simplicity. The technique is as follows: Five tenths cubic centimeter of physiologic solution of sodium chloride is placed into each of a series of test tubes in a rack, 1 cc. of the serum to be tested is taken up in a pipet and one half is run in the first tube and one half in the second. The mixture in the second tube is well shaken and half of its contents is put in the third tube. Half of the contents of the third tube, after thorough mixing, is placed into the fourth, and so on. In the course of dilution with the physiologic solution of sodium chloride, the serum is rendered colorless. From the last tube (colorless) 0.5 cc. of the contents is removed. To each tube there is now added 1 cc. of a 20 per cent solution of trichloroacetic acid. The mixture is well shaken and is poured into funnels made of filter paper and designated by fractional numbers the numerator of which is the number of the serum and the denominator is the number of the test tube. The funnels remain in the test tubes over night. The readings are made on the following morning. The sediment and the filter paper turn green in the presence of bilirubin, while in its absence both are a dirty yellow. The quantity of bilirubin is determined by multiplying the degree of solution by 1.56, since the bilirubin of the last dilution still having a greenish tint corresponds to 0.0156 mg. per cubic centimeter of serum or to 1.56 mg. per hundred cubic centimeters. According to this, funnels N/1, N/2 and N/3 contain 1.56, 3.13 and 6.25 mg. per cent respectively. These quantities are considered normal. Greenish tints in greater dilutions represent pathologic bilirubinemia.

\*Remarks on Relation Between Effect of Vitamins A and D and Content of Calcium Salts and Phosphates in Food H. Møllgaard — p 565  
Content of Pollen in Air in Hay Fever Season K. Baagø — p 570  
Field Dermatitis (Dermatitis Bullosa Striata Pratensis) A. Kissmeyer — p 574

**Vitamins A and D and Calcium Salts in Food**—From experiments on animals Møllgaard concludes that the danger of tetanic and osteoporotic conditions following the administration of vitamin D or A and D is most marked when the calcium content of the diet is low. On the other hand, hypercalcemic conditions are easily produced by the administration of too abundant amounts of calcium salts and these conditions are considerably aggravated by treatment with the vitamins in question.

## CHANGING CONCEPTS OF NUTRITION

CHAIRMAN'S ADDRESS

JAMES S MCLESTER, MD  
BIRMINGHAM, ALA

The day was when, in order properly to nourish the sick person, the physician told him what he must not eat, now, he is told what he must eat. This changing concept of nutrition marks a great advance in clinical medicine.

Until a decade ago, nutrition was the stepchild of medicine. True, for generations this science has been constantly advanced by a long line of brilliant investigators from Lavoisier to Graham Lusk, but physicians have been slow to give this knowledge practical application. This lack of interest was due in no small measure, I believe, to the semicharlatanism and wild faddism which have always flourished in this field and which have led many conservative physicians to give it a wide berth. Now a reversal of feeling has taken place. The great discoveries of recent years have excited the interest of every one, laymen and physicians alike, and today medical men are keenly alive to the vastly important part which nutrition plays in the prevention and treatment of disease, a radical change in the conception of the nutritive needs of the sick person has come about. This change is explained, I believe, by the order in which, in the evolution of modern medicine, the basic sciences have developed, cellular pathology coming early and present-day physiology late. Formerly, in planning the patient's food, physicians thought solely in terms of the local pathologic condition, of the harm they might do some impaired organ, now they think chiefly in terms of general physiology, of the good they can do the patient as a whole. This transition is signally characteristic of modern thought in nutrition.

All of this was foreshadowed twenty-five years ago by a complete about face in the treatment of typhoid. As an intern I saw the soldiers ill with this disease who returned in large numbers from the Spanish-American War, and two things stand forth in my memory: the miserably small amounts of food that were given these patients, and their desperately ill state. Today one sees a different typhoid. Now the patient is seldom very ill, the carphology and subsultus tendinum of those earlier days is a thing of the past, as is the muttering delirium, the distressing abdominal distention and the so-called toxemia, all because Warren Coleman demonstrated that the patient with typhoid must be adequately nour-

ished. No longer do physicians think chiefly of the pathologic changes in the small intestine but rather of the nutrition of the patient as a whole. Today he is given much more abundant food of relatively wide variety, and as a rule he gets well.

Witness the change that has come about in the treatment of gastric ulcer. The method that long prevailed was the semistarvation plan of von Leube, until finally Lenz showed that the cure of almost anything is made more difficult by starvation and pointed out the fallacy of such rigid food restriction. The regimen which he instituted and which was revised for the American stomach by Sippy is of value not merely because the more abundant food has a direct influence on the stomach but also because it keeps the patient in something like nutritive equilibrium. It promotes repair.

A grievous error of the past was the dietary limitation imposed on the patient with Bright's disease. In the treatment of all forms of nephritis the physician had in mind but one object, that of sparing the kidney, and reasoned that this could best be accomplished by drastic restriction of the protein intake. Because of limited vision the effects on the kidney of the degradation products of protein metabolism were feared, and in the interest in the local changes the patient himself was forgotten. Physicians entirely overlooked the fact that food proteins which are used for replacement purposes are not degraded to their end products and therefore can in no wise increase the burden on the kidney and, what is still more important, failed to realize that protein loss plus protein starvation must of necessity lead to a depletion of body proteins and thus eventually to a state of chronic inanition, which in turn retards all recovery.

If recovery is to be promoted, protein loss must be made good. The truth of this was first seen in the striking results obtained by Epstein when his nephrosis patients, with their heavy albuminuria, were fed large amounts of protein. Later this became still more evident through the observations of Van Slyke and his associates, who found that if the plasma protein deficit of glomerular nephritis is allowed to persist the patients fare badly, while, on the other hand, if the albumin loss is made good and the blood proteins are maintained at approximately the normal level, the patients as a rule go on to complete recovery. The accuracy of these observations has been abundantly attested by McCann in the excellent results achieved when he prescribed large amounts of protein for patients with glomerular nephritis. In some of McCann's patients the improvement was graphic. From such experiences it has been learned not only that rigid protein restriction in nephritis is bad but that if the patient is to be given the best opportunity for recovery he must be adequately nourished, and that of paramount importance is a

liberal, sometimes a large, intake of protein. Here, too, the medical profession has advanced from a consideration of local pathologic change to one of general physiologic function.

In the same category until recently was the patient with vascular hypertension. He was told that he must eat no meat, no eggs. I have no doubt that the resulting protein starvation imposed an additional handicap on many persons already suffering from heavy disabilities and that much unnecessary semi-invalidism resulted. From a better understanding of nutrition it is now known that instead of this one-sided diet the person so handicapped must have a well balanced ration, never excessive, but never lacking in any essential, such a diet as is best calculated to preserve the greatest degree of vigor for the longest period of years.

Even more recent is the change that has come about in the conception of the nutritive needs of the patient with diabetes. The earlier understanding of this disease was that it was merely a failure of carbohydrate utilization. It was thought of only in terms of carbohydrate metabolism and the patient's food was restricted accordingly. Then came insulin. This agent has helped enormously, and while it has not solved the riddle of diabetes it has pointed the way to one important truth, that is, that the entire animal economy, not merely a single metabolic fault, must be considered. In providing nourishment for the diabetic patient it has been learned that he must get adequate amounts of every class of food, particularly of carbohydrate, the very foodstuff that was formerly restricted with such rigor.

Even in tuberculosis, views have materially changed. The ability of the patient to store fat was once thought to be the best criterion of progress, and that to bring about a condition of obesity or near obesity was the acme of good treatment. Now it is known that such a condition imposes a real handicap. It is evident from a nutritional standpoint that the greatest good for the tuberculous patient can be accomplished by a diet that is liberal but not too liberal, that is, a diet that keeps him in a state of nutritive equilibrium and approximately at his ideal weight. This, infinitely more than a condition of overweight, encourages recovery.

In chronic arthritis every variation of dietary restriction has been played on, and almost everything, at one time or another, has come under the ban. Proteins were restricted because they increase the production of uric acid, fruits and tomatoes were forbidden, strange to say, because they contain acids, and sugars and starches were limited because a few students of arthritis have concluded that lowered dextrose tolerance is a salient feature of these disorders. No satisfactory clinical evidence, however, has yet been presented to show that such restrictions, even of carbohydrate, influence the course of arthritis. The feeling is gaining ground that, except for reduction of weight in the obese, most can be accomplished in a nutritive way for arthritic patients by warning against one-sided diets and by prescribing a fairly liberal ration which carries all nutritive essentials. It is coming to be realized that these unfortunate patients are destined to be sick a long time and that they should be permitted a ration which best insures against nutritive failure.

Even the nutritive needs of infancy and early childhood are today viewed with a much broader understanding. Those practitioners who were taught the elaborate milk formulas of thirty years ago marvel at the wide variety of foods given infants today, spinach,

carrots, beets, tomatoes, scraped beef, even sweet potatoes. They take almost anything and thrive.

I am tempted to hazard the prediction that this shift in the concepts of nutrition will extend to the obstetric practice of the future. That school of thought which restricts the protein quota of the pregnant woman's ration for fear of damaging the liver and thus producing eclampsia is, I believe, in error. And, too, those obstetricians who materially restrict all food in pregnancy in the effort to limit the size of the offspring and thus make labor easier are likewise, I fear, in error. During pregnancy the woman needs, more than at any other period of her life, an abundant diet which provides in adequate amounts all necessary food factors, not only carbohydrate and fat but proteins, vitamins and minerals as well. To deny her this, even in small degree, is to court disaster.

In conclusion I would call attention to the fact that these changing concepts of nutrition are not the result of vacillation or of an uncertain drift of opinion. Far from it. They express the broader understanding of man's nutritive needs that has come with the discoveries of recent years and represent the well considered application of knowledge gained, little by little, from painstaking research and careful clinical observation. This is the way of progress.

930 South Twentieth Street

## TREATMENT OF EMPHYSEMA

JONATHAN MEAKINS, MD

AND

RONALD V. CHRISTIE, MD

MONTREAL

Chronic pulmonary emphysema is the permanent overdistention of the alveoli and the decreased elasticity of the pulmonary tissues. It is not our purpose to discuss the different factors that may produce emphysema but rather how it interferes with respiratory and circulatory function and the means whereby these deleterious effects may be overcome.

Whatever the etiologic factor, the cause of the impairment of function in emphysema evidently lies in a loss of pulmonary elasticity. As this loss of elasticity progresses, the lungs can no longer resist the traction of the chest wall and they distend until a position approaching full inspiration is reached. The lung can now no longer deflate during expiration by the normal process of passive elastic recoil but has to be actively compressed by the extrinsic muscles of expiration. In other words, the lung has to be pulled on to make it distend and then has to be actually squeezed to make it deflate. This is a highly unnatural form of respiration and one that leads to a general disruption of the mechanics of pulmonary ventilation and circulation. It is difficult to dissociate the respiratory from the circulatory readjustments since they are interactive, but for the sake of clarity this will be attempted.

### RESPIRATORY READJUSTMENTS IN EMPHYSEMA

With the loss of elasticity the lungs distend, following the traction of the chest wall and leading to a marked increase in the volume of the functional residual

From the Department of Medicine McGill University Clinic, Royal Victoria Hospital.  
Read before the Section on Practice of Medicine at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 13, 1934.

air. This disturbs the ratio of functional residual air to the total capacity. In normal people the former is between 35 and 40 per cent of the latter, but in emphysema it may be as great as from 70 to 80 per cent. As a result of the same causes there is a more or less pronounced reduction in the vital capacity, and their influence is also reflected in the type of breathing. At rest it may be quite similar to the normal but on exertion the volume cannot be properly increased and therefore it becomes rapid and relatively shallow. In fact, in severe cases this is present at rest. In other words, the resting tidal air and the vital capacity may approximate equality.

Normally, expiration is a passive act accomplished by the elastic recoil of the lungs. With loss of pulmonary elasticity the lung will no longer recoil but has to be compressed by an active expiratory effort with the generation of a positive intrapleural pressure, to which the thoracic cage in a man is wholly unsuited. The diaphragm is a muscle of inspiration and is not constructed to resist any such increase in intrathoracic pressure, which is bound to displace it downward, with subsequent impairment of tone and range of contractility. This downward displacement of the diaphragm can be prevented only by contracting the muscles of the abdominal wall, since a sufficient increase in the intra-abdominal pressure will support the dome of the diaphragm. Unfortunately in emphysema the abdomen is apt to be relaxed and pendulous and this excessory aid to expiration is not present. The importance of this state of affairs has not been sufficiently appreciated and must be forcibly emphasized.

In addition, on account of the overexpanded and melastic condition of the lungs, the diaphragm at the

is a difficult and fatiguing procedure, also actually leads to an interference with the primary purpose of respiration, namely, an adequate gaseous exchange between the blood and the alveolar air. With the loss of elasticity there is a change in the distribution of ventilation throughout the lung. No longer are the alveoli equally ventilated, but the superficial, distended, ischemic and relatively functionless alveoli are over-ventilated at the expense of the deeper and more healthy

Chart 2—Pulmonary distensibility and elasticity. Minimal tuberculous lesion at right apex. Tracing to show that the point of maximum distention corresponds closely to the time when the intrapleural pressure is most negative.

alveoli, which are underventilated. In all cases of emphysema recognizable clinically, there is a definite reduction in oxygen saturation of the arterial blood. This fortunately develops slowly and therefore allows the body to become accommodated to the anoxic change of its internal environment. This is reflected first in the comparative comfort of many patients with a reduced arterial oxygen saturation, which if produced suddenly would give rise to the most acute dyspnea, and, secondly, in the increase of hemoglobin and polycythemia that develops. These disturbances explain the cyanosis, which is a frequent occurrence in this condition. There is also usually an increase in the carbon dioxide of the arterial blood, which is compensated for by an increase in the bicarbonate reserve. The respiratory distress and the impairment of hemorespiratory exchange are proportionate to each other.

#### CIRCULATORY READJUSTMENTS IN EMPHYSEMA

Disturbances of the circulation have always been considered important complications of emphysema. They can properly be considered in two phases, namely, increased venous pressure and right heart failure, both of which are directly due to the reduced elasticity of the lungs and the increase in intrapleural pressure. The influence of these two conditions on the circulation cannot be separated, as they are themselves interdependent. In normal subjects there is a small but definite pressure gradient between the vena cavae and the right auricle. This is largely governed by the negative intrathoracic or intrapleural pressure. When this becomes positive over a greater part of the time, an increase in the venous pressure takes place during this period. As the degree of emphysema and therefore the increase in intrapleural pressure becomes progressively pronounced, so will there be a rise in venous pressure and this in turn will tend to progress to right heart failure. The progress is slow but in

Chart 1—The vital capacity in four cases of emphysema showing the overstretching on deep inspiration and the difference between the volume of reserve air taken alone and that taken at the end of a test for vital capacity. C, complemental air; R, reserve air; V, vital capacity. The irregularity in the resting respiratory level is also well shown.

end of expiration cannot rise to its normal position, as the contents of the thorax are too voluminous to allow it to do so.

Such profound disturbances in respiratory function, besides making the patient ever conscious that breathing

The heart in emphysema exhibits hypertrophy of the right ventricle *pari passu* with the pulmonary lesion. This would strongly point to an increase in pressure in the pulmonary arteries. It is conceivable that this might be brought about either by an intravascular resistance due to the anatomic changes in the lung or to diminution of the so-called pumping action of the lungs, or to an actual compression of the pulmonary circulation during the period of increased intrathoracic pressure. The first two are problematic, as they have been surmised but not proved, the last has been demonstrated

Chart 3—The intrapleural pressure in emphysema. Initial 40 cc pneumothorax on the right side. Pressure fluctuates around that of the atmosphere. With deep inspiration the negative intrapleural pressure is held rather than increased and when inspiration is complete pressure returns to atmospheric pressure to compare with normal see Christie and McIntosh (*J Clin Investigation* 13:279 [March] 1934 figure 5).

It has also been found that circulatory failure, like the disturbances of hemorespiratory exchange, is parallel to the increase of intrapleural pressure.

The patient with advanced emphysema is indeed in an unfortunate position. The muscles of inspiration are already in the inspiratory position when inspiration commences. A greater amount of work is required to distend the lung, and a large proportion of the air that is inspired is wasted on the peripheral functionless alveoli. Even after this wasted effort, the lungs cannot passively relax except as the result of an unnatural expiratory effort. As respiratory compensation fails, imperfect aeration of the blood occurs and a vicious circle is established, with increasing demands for hyperventilation and decreasing ability to ventilate.

#### TREATMENT

The anatomic state of the emphysematous lung is beyond repair. Its treatment, therefore, is restricted to the amelioration of the resulting functional defects.

The difficulties of expiration and the paradoxical movement of the diaphragm can best be relieved by increasing the intra-abdominal pressure through the wearing of a tight abdominal binder.<sup>1</sup> This raises the diaphragm toward its normal expiratory position and at the same time supports it in this position during the active muscular expiration. This procedure undoubtedly gives these patients symptomatic relief of their consciousness of respiration and also seems to save them considerable respiratory fatigue. There is some difference of opinion as to how this is brought about. In the case of pregnancy reported by Gordon in which he recorded the intrapleural pressure, he found it to be

definitely and progressively increased. Alexander, on the other hand, states that in a few cases it is decreased, in fact, becomes negative during expiration. We have been hesitant to make a thorough study of this point as we considered that the dangers of pulmonary rupture were too great. Alexander also reports, giving actual amounts, pronounced increases in the vital capacity. The increase averaged 39 per cent. The largest was 77 per cent (1,800 cc without to 3,200 cc within the belt). We have not been able to corroborate this, in fact, our tracings of the vital capacity, reserve and complementary air in subjects trained in this form of respiratory gymnastics do not show any conspicuous or constant differences in these measurements with or without the belt.

It has been mentioned that in emphysema there is a reduced oxygen saturation of the arterial blood. This gives the patients the deep bluish cyanosis so characteristic of the disease. It varies greatly from time to time. Temporary relief can be afforded by the inhalation of air enriched with oxygen. It is impossible to carry this out during the daily activities, but disturbed sleep is often distressing. This can be greatly relieved by oxygen therapy for an hour or so before going to sleep. The duration of the symptomatic improvement is surprising.

Cardiac failure is to be expected in progressive cases. The usual measures for the conservation of energy should be instituted for its prevention. In the acute attacks, free venesection should be done promptly. For the rest, the treatment should be such as would be indicated in cardiac failure due to other causes.

If it is true that the intrapleural pressure is increased by an abdominal belt, its use in time may aggravate the embarrassment of the pulmonary circulation. This may explain how some patients find it impossible to tolerate the belt even though it may give them some respiratory relief.

Chart 4—Spontaneous pneumothorax in emphysema. Lung evidently punctured while pneumothorax was being given with formation of valvular bronchopleural opening. No immediate change in pleural pressure or tidal air but progressive diminution in the latter and increase in the expiratory pressure can be observed until at end of tracing a pressure fluctuation of +132-90 only yielded a tidal air of 60 cc. At this point 2100 cc of air was removed from the pleural cavity with complete relief of symptoms.

Lastly, any condition such as chronic bronchitis or asthma, which tends to increase the distention of the lungs, should be treated. The treatment of cough is the treatment of its cause, but usually an abdominal

<sup>1</sup> The use of a suitable binder in such pulmonary conditions was suggested by three separate workers. Christie at the meeting of the American Society for Clinical Investigation May 8, 1933 and Alexander and Gordon at the meeting of the Association of American Physicians May 9, 11, 1933.

binder will relieve the distress that so often accompanies coughing in these cases. Most cases of emphysema present some asthmatic tendency and ephedrine is always worth a trial.

#### ABSTRACT OF DISCUSSION

DR S ADOLPHUS KNOPP, New York. The idea of an abdominal bandage for sufferers from emphysema is excellent and I am inclined to believe that it should be of equal advantage for asthmatic patients. There is, however, an exercise which I might call a physiologic adjuvant in the treatment of emphysema. It is equally helpful in asthmatic attacks. It consists of supinating the arm and forearm and pressing them against the sides of the chest along the axillary line. As is well known, it is expiration that is so difficult for the emphysematous and asthmatic patient. Of the 1,200 cc of tidal air and 500 cc of residual air, quite a quantity can be expelled by this pressure movement and thus relieve the most distressing symptoms of emphysema and asthma. If in addition to this, the patient uses diaphragmatic respiration rather than costal and is careful with his diet, he will avoid accumulations of gas in his abdominal region, and will be rendered more comfortable. The improvement of the portal circulation by diaphragmatic respiration is a decided advantage to this class of patient. Of course, he must not resort to this exercise of supinating the arms to the extent of getting overtired and must avoid all strenuous physical exertion. This precaution is one to which all emphysematous and asthmatic patients must adhere.

#### INTENSIVE LIVER EXTRACT THERAPY OF SPRUE

C P RHOADS, MD  
AND  
D K MILLER, MD  
NEW YORK

The effective treatment of sprue is a problem of considerable practical importance in spite of the fact that therapeutic methods which are occasionally successful have been at hand for many years. One serious difficulty lies in the fact that different individuals, presenting an apparently identical clinical picture, manifest wide variations in the amount of specific therapy that they require to effect clinical cure. Moreover, the available information regarding the treatment of sprue is confusing, since the various therapeutic procedures in use appear to be so unrelated and the clinical results obtained from them have been so inconstant that it has seemed impossible to draw up a general rule of treatment that would be applicable to all cases.

More detailed analysis of the existing therapeutic methods in the light of present knowledge makes it clear that a general rule of treatment can be formulated and, furthermore, that from the therapeutic results an understanding of the etiologic mechanism of the disease syndrome may be obtained. Such an understanding is of importance in treatment, since without it various therapeutic procedures seem to be purely empirical, and when doubt as to the rationale of a procedure exists the determination to carry it through to the desired end is frequently wanting.

Prior to 1927 the treatment of sprue was almost entirely dietary. The accepted policy was to restrict the intake of fat and of carbohydrate and to depend on different single and apparently dissimilar food materials as the principal sources of nutrition. Thus in turn liver diets, meat diets, milk diets, banana diets and strawberry diets were all recommended and were frequently effective when employed early in the course

of the disease. Complete and permanent cure occasionally followed such treatment but early and severe exacerbations were the rule and a stage of the disease was eventually attained at which dietary measures were ineffective.

Baumgartner<sup>1</sup> showed that the feeding of these diets was specific in promoting hematopoiesis. He applied to sprue anemia a procedure devised by Minot and his associates<sup>2</sup> for evaluating the effectiveness of specific therapy in pernicious anemia. The method was based on the fact that the percentage of reticulocytes in the circulating blood increased very markedly at the onset of a true remission. Reticulocyte rises were induced by feeding to individuals with sprue anemia certain diets which were known to be effective in the treatment of that disease but which did not contain liver or other material known to be curative in pernicious anemia. This observation was evidence that some constituent of the diet was specifically required for hematopoiesis in sprue anemia and that this dietary constituent was not the liver fraction so effective in the treatment of pernicious anemia. This difference in the response to therapy was the more incomprehensible when the striking hematologic similarities between the two anemias were considered. Two problems were then at hand: first, to ascertain the presence of some common factor in the diets known to be effective in the cure of sprue and, second, to show the relationship of such a common factor to the substance effective in pernicious anemia, a disease that is symptomatically and hematologically similar to sprue.

A more detailed knowledge of nutrition makes it clear that the seemingly dissimilar diets do possess one factor in common, a relatively high content of water-soluble vitamin. Since this appears to be the only common factor, it seems probable that the effects obtained in the treatment of sprue by feeding these diets are due to the water-soluble vitamin which they contain. It is an established principle in the study of nutritional factors that, if a demonstrable physiologic effect can be induced by feeding any one of a variety of substances in which only one particular vitamin is common to all, the effect will occur only in the presence of a deficiency of that vitamin in the body of the test animal. Since several different diets are irregularly effective in the treatment of sprue and these diets contain only the water-soluble vitamin as a common factor, it seems probable that a lack of that vitamin exists in certain cases of the disease. Furthermore, the existence of such a lack suggests that it is perhaps causal, that is, that sprue is a disease due in some instances at least to a deficiency of some fraction of the water-soluble vitamin complex. Since dietary treatment is not always effective, however, it follows that in other instances one or more additional or complicating etiologic factors are involved. Studies of the factors concerned in the etiology of pernicious anemia, a disease similar in many respects to sprue, have given the clue to the nature of the complicating factors concerned in the etiology of the latter disease.

In 1925 Minot and Murphy<sup>3</sup> showed that whole liver was specifically effective in the cure of pernicious anemia. Bloomfield and Wyckoff<sup>4</sup> fed whole liver to

1 Baumgartner, E. A. and Case, C. E. Clifton M. Bull. 16: 183 1930.

4 Bloomfield, A. L. and Wyckoff, H. A. California & West. Med. 27: 659 (Nov.) 1927.

individuals suffering from sprue and in 1927 published an account of clinical cures resulting from such treatment. In the following year West<sup>5</sup> reported remissions following the treatment of sprue with that fraction of liver which had been shown by Cohn, Minot and their associates<sup>6</sup> to be effective in pernicious anemia. Liver extract, then, as well as diets rich in the water-soluble vitamin, may be therapeutically effective in sprue. To

Chart 1—Hematologic changes following the intramuscular injection of 10 cc of liver extract daily. For five weeks previous to this 2 cc of the same material was administered daily by intramuscular injection without improvement.

establish the etiologic similarity between sprue and pernicious anemia, it remained only to prove that the water-soluble vitamin could induce remissions in the latter condition. Such an effect was suggested by the studies of Castle and his associates,<sup>7</sup> which showed that a dietary constituent contained in beef muscle was acted on by a substance present in normal gastric juice to produce a third substance potent in producing remissions in pernicious anemia. The gastric juice of patients with the disease was not effective in forming the hematopoietic principle by interaction with the dietary factor. Hence, a deficiency in the gastric secretion was clearly causative of pernicious anemia. Other investigators showed that the livers of patients with pernicious anemia who lacked adequate gastric secretion were devoid of the hematopoietic principle present in normal livers. It was apparent that the product of the interaction of a dietary factor and normal gastric secretion was stored in the liver, where it was available for clinical use as liver extract.

It appeared from these investigations that a dietary constituent as well as normal gastric secretion was required for hematopoiesis. In 1931 Castle and his associates<sup>7d</sup> pointed out that a disease similar to pernicious anemia should develop if there was an insufficient intake of the dietary constituent, a defect of the gastric juice or defective absorption of the product of the interaction of these factors. Sprue was similar to pernicious anemia and was due in some instances to lack of a diet rich in the water-soluble vitamin. Clearly, if the dietary factor involved in the causative mechanism of pernicious anemia could be shown to be the water-soluble vitamin, the link between pernicious anemia and sprue would be established.

The next step was to establish the dietary factor as being related to the water-soluble vitamin. Wills<sup>8</sup>

described remissions induced in cases of tropical macrocytic anemia by feeding an extract of yeast, which was rich in that vitamin. Castle and Rhoads<sup>9</sup> observed similar responses resulting from the use of the same yeast extract in cases of sprue. This was confirmatory evidence that a relatively simple preparation rich in vitamin B complex was effective in that disease. An exactly similar effect was shown by Strauss and Castle<sup>10</sup> to occur if the same yeast extract was incubated with gastric juice and fed to patients with pernicious anemia. Reticulocyte rises and improvement of blood values occurred uniformly. Neither the yeast extract nor the gastric juice was effective alone. This indicates that the dietary factor, given as meat in the original experiments of Castle, was contained in a yeast extract rich in the water-soluble vitamin and that an interaction with gastric juice was required for it to be effective in hematopoiesis in pernicious anemia. Thus the only difference between certain cases of sprue and of pernicious anemia was that a substance rich in the water-soluble vitamin was therapeutically effective per se at least in certain cases of sprue, whereas it was effective in pernicious anemia only after it had been incubated with normal gastric juice. The dietary factor in the two conditions was the same. Simple dietary lack, while apparently causative in certain instances, was clearly not the only factor involved in the production of all cases of sprue.

Since symptomatic similarities between sprue and pernicious anemia exist, and since orally administered liver extract, a material effective in pernicious anemia, was occasionally effective in cases of sprue, which had failed to respond to diet alone, it seemed probable that the lack of a gastric secretory factor might contribute at least to the causative mechanism of sprue in the way in which it had been shown to be causative in pernicious anemia. The observation by Rhoads and Castle<sup>11</sup> of the similarity between the pathologic alterations of the bone marrow in the two conditions is further evidence that they possess some etiologic factor in common. The study by Castle and Rhoads<sup>9</sup> of a large number of cases of sprue in Puerto Rico showed that the gastric dysfunction obtaining in per-

Chart 2—Hematologic changes following the daily intramuscular injection of 10 cc of liver extract.

nicious anemia did play a part in the production of symptoms in certain instances. This was clear from the fact that in some cases the addition of normal gastric juice to substances rich in the water-soluble accessory food factor was required before a remission

could be effected. This was evidence that there was a lack of anti-pernicious anemia factor in the gastric juice of the patients tested. In the same publication it was reported that in other instances remissions could not be induced even though both the dietary factor and the gastric factor were supplied to the intestinal tract. This was also the case when liver extract, a material supposed to represent the product of the interaction of those two factors was given by mouth, although when a much smaller amount of liver extract was administered parenterally, maximum responses were obtained. As suggested by Castle,<sup>12</sup> for pernicious anemia this fact can indicate only that the effective material either was not absorbed from the intestinal tract or was broken down in it. The former hypothesis was considered to be the most probable, since sprue may result from surgical intervention with the absorbing surface of the bowel, moreover, sprue is frequently associated with secondary deficiencies of such dietary constituents as calcium and iron, elements not likely to be destroyed in the intestinal tract.

**loss of weight** For five weeks before entry to the hospital the patient had received daily intramuscular injections of liver extract, the amount given at each injection being that derived from 10 Gm of whole liver. At the onset of the disease the patient weighed 215 pounds (97.5 Kg), the weight on admission was 92 pounds (41.7 Kg).

**Examination**—The patient was emaciated and semicomatose, with incontinence of urine and feces. The mucous membranes were very pale and had a definite icteric tint. The tongue was smooth. The abdomen was tympanitic, and audible peristalsis was present. There was pitting edema of both legs.

Gastric analysis showed free hydrochloric acid only after the injection of histamine. Results of the laboratory examination were: red blood cells, 1,130,000, hemoglobin, 30 per cent, white blood cells, 5,250, color index, 1.42, mean corpuscular volume, 115 cubic microns, reticulocytes, 10 per cent.

**Course in Hospital**—Vomiting occurred after every feeding. There were five or six large yellow stools a day. Intramuscular injections of solution liver extract-Lilly were given daily for two weeks, each being of 10 cc, an amount derived from 50 Gm of whole liver. On the sixth day there was a reticulocyte count of 22 per cent. The diarrhea and vomiting disappeared. The injections were continued twice a week until

Chart 3—Hematologic changes following the daily intravenous administration of 20 cc of liver extract

It appears, then, that clinical sprue may arise in three ways: by dietary lack, by lack of the gastric enzyme that is absent in pernicious anemia, or by inability to absorb the product of the interaction of the first two. Clearly, any one of the three factors may be causative or any combination of the three may exist. Furthermore, differences in the relative importance of the part played by each of the three might account for variations in the clinical manifestations.

In view of the facts presented, it becomes clear that the desideratum in the treatment of sprue is to place the product of the interaction of the dietary factor and the gastric enzyme, that is, liver extract, as near to the site of utilization as possible in as large amounts as may be required. Our purpose in this communication is to indicate what parenteral route is most effective and what amounts of material are required to induce remissions in the most refractory cases. If methods effective in those cases were to be applied as a general rule in the treatment of all, therapeutics would become simplified and the period of the patient's incapacity would be materially reduced.

#### REPORT OF CASES

**CASE 1—History**—M. G., an American woman, aged 47, who had resided for twenty years in Puerto Rico had had sprue for four years with glossitis, stomatitis, diarrhea and

discharge. The patient gained rapidly in weight and left the hospital six weeks after admission, with an erythrocyte count of 3,710,000 and hemoglobin 75 per cent. One year later the patient's weight was 187 pounds (84.8 Kg) and she was symptom free. She has received the same amount of liver extract twice a month since her discharge.

**CASE 2—History**—R. D., an American woman, aged 50, who had lived for twenty-one years in southern China, entered the hospital complaining of diarrhea of seven years' duration, her illness following an afebrile attack of diarrhea lasting six weeks. Subsequent attacks occurred during the first year. Early in the second year soreness of the tongue and mouth developed and the diarrhea was persistent. Relief of symptoms followed a diet of sour milk and liver. During the fourth year from the onset of symptoms, improvement did not follow the same treatment and the patient returned to this country, where she was free from symptoms for six months. The period of relief was again followed by severe abdominal distress and diarrhea. About six weeks before entry, weakness, shortness of breath and pallor appeared, and she was confined to bed. Three vials of liver extract-Lilly were administered orally each day for three months without relief of symptoms.

**Examination**—The patient was markedly emaciated and appeared extremely ill. The skin and mucous membranes had a lemon-yellow tint and were pale. There was atrophy of the papillae along the borders of the tongue, with furrows over the dorsum. The abdomen was slightly distended and tympanitic. The spleen was palpable. There was pitting edema of both ankles. Gastric analysis showed free hydrochloric acid only after the injection of histamine. Laboratory examination showed red blood cells, 820,000, hemoglobin, 22 per cent.

color index, 1.34, mean corpuscular volume, 131 cubic microns, icterus index, 20, reticulocytes, 1 per cent

**Course in Hospital**—Daily intramuscular injections of solution liver extract-Lilly were given for two weeks. Each injection was of 10 cc, an amount derived from 50 Gm of liver. On the sixth day after the first injection there was a reticulocyte rise of 42 per cent. The day after the first injection the patient had one formed bowel movement, although there had previously been five or six loose stools daily. The reticulocyte response was followed by a rise of the red count and hemoglobin values. The patient had no further diarrhea unless a longer period than two weeks elapsed between injections of liver extract. She was discharged seven weeks after entry with an erythrocyte count of 4,170,000 and a hemoglobin level of 73 per cent. For two years since discharge the patient's erythrocytes have been maintained at about 4,500,000 per cubic millimeter with treatment twice a month. She has been able to eat a normal diet and has had no diarrhea.

**CASE 3—History**—M G, a Puerto Rican woman, aged 63, had had sprue for eighteen years before entry. For five years, soreness of the mouth and tongue had been present. The patient had lost from 30 to 40 pounds (13.6 to 18 Kg) and had noticed extreme weakness during the two months preceding her admission.

**Examination**—The patient was emaciated and markedly pale. The tongue was smooth. The abdomen was moderately distended and peristalsis was audible. The spleen was just palpable. There was pitting edema of both legs.

Gastric analysis showed free hydrochloric acid only after the injection of histamine. Laboratory examination showed red blood cells, 1,000,000, hemoglobin, 30 per cent, white blood cells, 2,250, mean corpuscular volume, 120 cubic microns, color index, 1.50.

**Course in Hospital**—The patient was given 12 Gm of a commercial yeast extract daily for twenty days, without relief of anemia or diarrhea. During the following ten days 200 cc of normal human gastric juice was given daily without any therapeutic response. During the succeeding ten days human gastric juice and Vegex in the aforementioned amounts were incubated together and fed daily. This digest is known to be effective in pernicious anemia. There was no improvement in blood values or amelioration of the diarrhea. Since the patient's condition was serious, 20 cc of Parke, Davis & Co liver extract prepared for intravenous use was administered intravenously each day. On the eighth day after the institution of treatment the reticulocytes were 27 per cent. This was followed by improvement in the blood values and cessation of the diarrhea. The daily treatment was continued for two weeks and then one injection was given twice weekly until discharge three and a half months after entry. At the time of discharge the erythrocyte count was 4,000,000 and the hemoglobin 80 per cent. Treatment has been continued at intervals of two weeks for one year, and during that time the patient has been symptom free and has maintained normal blood levels.

**CASE 4—L N**, an American woman, aged 45, who had resided in China for twenty-one years, had suffered from sprue for fifteen years. The presenting symptoms were stomatitis, glossitis, proctitis and diarrhea. Nine years before admission a remission had followed the taking of a high protein, low fat and low carbohydrate diet. For three years before admission, nausea and vomiting with marked loss of weight had been present. For six months the patient had been in bed and able

to retain only milk. During the three months immediately preceding admission she had received intramuscular injections twice a week of 2 cc of liver extract, an amount derived from 10 Gm of whole liver. No improvement had resulted from this therapy.

**Examination**—The patient was markedly emaciated. There was pallor and a faint yellow color of the skin and mucous membranes. The tongue showed atrophy of the papillae. There was edema of both legs.

Laboratory examination showed red blood cells, 860,000, hemoglobin, 27 per cent, white blood cells, 2,500, mean corpuscular volume, 136 cubic microns, color index, 1.54. Gastric analysis showed free hydrochloric acid only after the injection of histamine.

**Course in Hospital**—The patient was given 20 cc. of liver extract-Parke, Davis & Co intravenously each day during her stay in the hospital. On the seventh day of treatment the reticulocytes had risen to 43.2 per cent. This was followed by an increase in the number of erythrocytes and of the hemoglobin content. Diarrhea did not occur after the injections of liver extract were begun. The patient's appetite improved and she was discharged three weeks after entry with an erythrocyte count of 3,040,000 and hemoglobin of 67 per cent.

#### COMMENT

The four cases of sprue reported all failed to respond to some form of specific treatment but did finally improve under intensive parenteral therapy. They were the only ones in a series of twelve cases of sprue similarly studied and treated in which a clear-cut comparison between different methods of treatment could be drawn. In all four refractory cases a steady, progressive increase in the severity of the disease had taken place in spite of supposedly adequate therapy employing agents that were known to be specifically effective. When moribund, all were finally treated with massive doses of liver extract, parenterally administered, and in all a prompt, dramatic and complete remission was effected. All have been maintained in good health by means of injections of liver extract at intervals not exceeding one month.

In addition to being completely refractory to any sort of oral therapy, two of the individuals had received persistent and supposedly adequate parenteral treatment without improvement. It thus appears that a well defined threshold requirement for liver extract exists in certain cases of sprue, a threshold that must be exceeded before a remission can be established. When such a refractory case is encountered intravenous therapy is indicated, not only because it is more effective in raising the concentration of the required substance in the blood stream but also because it is the only route by which the required amount of material can be administered without causing serious discomfort and perhaps disability to the patient. Any patient with sprue admitted for treatment now receives intravenously an amount of liver extract<sup>13</sup> derived from 50 Gm of liver each day until a clear-cut remission has been established.

The liver extract preparation found to be most effective is a relatively simple, unconcentrated product. Evidence is at hand that a certain loss of activity results from too great refinement and concentration. Patients with sprue have failed to improve on intramuscular injection of a large amount of a highly refined and concentrated product although a full remission has been effected by the use of a much smaller amount of material more simply prepared.

The mechanism of the production of the increase in the threshold requirement for liver extract is at present

Chart 4—Hematologic changes following the daily intravenous administration of 20 cc of liver extract

unknown. An analogous situation may be observed in animals, however, in experimentally induced disease states due to the lack of certain accessory food factors. One of these experimental deficiencies is canine black tongue, a condition considered by Goldberger and Wheeler<sup>14</sup> similar to pellagra in human beings and due to a lack of the heat-stable, water-soluble vitamin. In black tongue a refractory state may be induced if treatment is kept at the minimum required for preservation of life during repeated acute attacks. Eventually no amount of material rich in water-soluble vitamin will effect improvement, although a minute amount of the same substance is prophylactically effective.

The amount of treatment required to maintain a person with a high threshold requirement in good health, once a full remission has occurred, varies widely in different individuals. In one instance (case 2), intramuscularly administered liver extract is required at intervals of two weeks. If the treatment is delayed, gastro-intestinal symptoms recur and persist until liver extract is administered. In other individuals, treatment once in thirty days is sufficient to prevent recurrence.

As previously discussed, the effectiveness of liver extract in the treatment of sprue, coupled with other known facts, clarifies the etiologic mechanism of the disease. The efficacy of intensive treatment of cases refractory to less adequate measures is further evidence of the specificity of the effect of liver extract. The requirement of certain individuals for very large amounts of effective material administered parenterally is evidence of a threshold requirement that must be exceeded before a physiologic response can occur.

The emphasis that has been placed on the purely hematologic responses of pernicious anemia to liver has obscured the fact that corresponding improvement of the lingual and gastro-intestinal symptoms occurs. This was pointed out by Minot and Murphy in their original communications and has been commented on by others. The idea of treatment by diet of a gastro-intestinal disorder, such as sprue, is so thoroughly ingrained in the medical consciousness that it is difficult for it to abandon the conception of some beneficial quality of the diet, simply as a regimen. The foregoing discussion should serve to indicate that the occasional effectiveness of diet in the treatment of sprue is largely based on its ability to supply the water-soluble vitamin. Diet is, at best, an uncertain method of obtaining "liver extract" for the internal economy of the organism. By the use of parenteral liver extract the obstacles of dietary defect, gastric dysfunction and intestinal malabsorption are at once effectively surmounted.

#### SUMMARY AND CONCLUSIONS

1 Four cases of sprue were refractory to ordinarily effective treatment. Clinical cure followed intensive parenteral liver extract therapy.

2 The use of liver extract in sprue is indicated by the etiologic mechanism of the disease.

3 Sprue frequently requires much more intensive treatment with liver extract than does pernicious anemia.

4 The frequent parenteral administration of large amounts of liver extract is the therapeutic procedure of choice in sprue and should be continued until a remission is established.

## NORMAL CEREBROSPINAL FLUID DYNAMICS IN SPINAL CORD TUMOR SUSPECTS

JAMES L. POPPEN, M.D.

AND

LEWIS M. HURXTHAL, M.D.

BOSTON

As the result of the efforts of Ayer<sup>1</sup> and Stookey,<sup>2</sup> the technic of eliciting abnormal changes in cerebrospinal fluid dynamics has become so refined that an obstruction in the spinal canal can be detected earlier in the disease than formerly. Cases have been reported, however, in which tumors were found that appeared large enough to block the entire canal but normal dynamics were shown by lumbar puncture. The question therefore arises, What size must a tumor be in relation to the spinal canal before there are any demonstrable changes in dynamics? Patients have frequently been known to suffer from pains for years which were thought due to rheumatism, sciatica, sacro-iliac disease or neuritis, before any objective symptoms were detected to suspect an intraspinal lesion. In such instances a problem as to the value of a lumbar puncture always arises, especially when the tumor does not obliterate the subarachnoid space.

Elsberg<sup>3</sup> states that in about 20 per cent of the patients with spinal cord tumors the Queckenstedt test (jugular compression) may be expected to be negative. This statement was made before the refined technic of both Ayer and Stookey were proposed. The present percentage of a negative Queckenstedt test is much less if done by those who are familiar with the technic and careful in following its details. Too much emphasis cannot be laid on this. The details that seem most insignificant are sometimes very important. Nurses at times are careless in cleaning the manometers and valves before sterilization. The most accurate readings will be obtained if the manometers and valves are autoclaved instead of boiled, otherwise droplets of water are likely to remain on the inside of the manometer, thus forming pockets of air and increasing capillary attraction. This may make some difference in the rise and fall of the spinal fluid when the pressure readings are taken. A fairly reliable test to make one confident that the needle is in the subarachnoid space is to have the patient strain or cough. Following this there should be a rapid rise and fall in spinal fluid pressure, which is at once followed by the normal amplitude of the respiratory and pulse oscillations.

Our purpose in this paper is to give an adequate explanation of the occurrence of normal pressure changes during the Queckenstedt test in the presence of a spinal cord tumor. Such a case has recently come under our observation, the history of which is as follows:

M. S., a girl, aged 21, unmarried, came to the clinic complaining of pains on the right side of the abdomen, which had been present intermittently for two years with no associated nausea or vomiting. At first the pains were located mainly in the right

upper quadrant. A gallbladder visualization showed normal function. The pains were aggravated by sudden twisting or bending of the neck and also by coughing. There was marked constipation but there were no bladder disturbances. There was a slight feeling of stiffness in the right leg for about two weeks previous to her entrance to the hospital. The rest of the history was irrelevant.

Physical examination showed moderate superficial and deep tenderness in the right lower quadrant. The abdominal reflexes were brisk and equal. The patellar and achilles reflexes on the right were markedly hyperactive (+++) and slightly less active on the left (++) A bilateral Babinski reflex was present. A very slight relative hypesthesia could be detected over the first and second lumbar skin areas on the right. Vibratory sense over the right internal and external malleoli was slightly diminished. The lumbar puncture showed an initial pressure of 120 mm of water. Prolonged jugular compression brought an immediate rapid response, the fluid rising rapidly to 260 mm and descending with the same speed on the release of the jugulars, the patient breathing normally throughout the procedure. The fluid, when compared with water, was slightly tinged with yellow. The total protein of the spinal

An artificial spinal canal with a partial block (C). A spinal puncture needle with manometer (A) attached is inserted into the caudal end corresponding to the cisterna magna. Another spinal puncture needle with manometer (B) is attached to the caudal end representing the fourth lumbar interspace. The diameter of the bore of the needle at C can be varied at will. The rubber tube (D) filled with water serves to transmit pressure to the canal in the same manner as compression of the jugular veins. By compressing the rubber tube no changes occur in the rise and fall of the water in either manometer as long as the diameter of the opening at C is equal to or greater than the diameter of the bore of the spinal puncture needles. As soon as the diameter of the opening at C is less than that of the spinal puncture needles there is an immediate lag in the rise and fall in the manometer (B) when the pressure is applied to the rubber tube (D).

fluid was 60 mm per hundred cubic centimeters. Iodized poppy-seed oil injected into the cistern twenty-four hours later stopped at the seventh thoracic vertebra, a few drops of the oil passed the obstruction after several hours. A laminectomy revealed a firm neurofibroma which was large enough to cause a pressure furrow in the spinal cord. There were no adhesions.

It is possible therefore to have a fairly large tumor in the spinal canal which does not give any signs of obstruction by the Queckenstedt test. To determine how large a spinal cord tumor must be before a partial block can be detected by lumbar manometric readings is obviously difficult because of the varying shapes and structures of the tumor. In considering this case in relation to hydrodynamics we concluded that as long as the unobstructed area at the site of the tumor was as large as the bore of the lumbar puncture needle

there could be no abnormal dynamics. In view of Weed's<sup>4</sup> belief that the dural tube in live mammals may be considered fairly though not absolutely rigid, we attempted to demonstrate our conclusions as follows. Two cylinders, closed at each end by cork stoppers, were connected by a large needle, as shown in the accompanying illustrations. A rubber tube was attached to the proximal cylinder by a size 18 gage spinal puncture needle. The system was then filled with water and the rubber tube clamped. This, then, was to represent the spinal canal with a partial block. The rubber tube could be used to increase the pressure in the cephalad end of the canal at will by pressing it. A size 18 gage lumbar puncture needle was then inserted through the caudal cork and a manometer attached. By compressing the rubber tube, the increased pressure was indicated by an immediate and rapid rise of the fluid in the manometers. It was also found that, by changing the size of the opening at the artificial block, a rapid rise and fall of the fluid occurred in the manometers by pressing the rubber tube intermittently. There was no change from the normal until the size of the opening in the block was definitely less than the size of the opening in the lumbar puncture needles. In other words, if the cross sectional area of the bore of the needle used in the spinal puncture is of the same order of magnitude as the effective cross sectional area not blocked by tumor in the spinal canal, no abnormal pressure changes in the dynamics should occur.

Another 18 gage needle was inserted in the cephalad cylinder and a manometer attached. No changes occurred in dynamics in either manometer until the size of the opening at the block was less than that of the needles used in either end. Thus, when the diameter at the partial block was made smaller, there was a lag in water at B and a rapid rise and fall in water at A when the rubber tube was compressed. This would suggest that a partial block can be detected more quickly by a combined cisternal and lumbar puncture than by lumbar puncture alone. Thus it is very important to do the combined punctures when a questionable change in the dynamics is found during a lumbar puncture.

Thus, we believe, explains why the cerebrospinal fluid dynamics are normal in a small percentage of relatively large spinal cord tumors. In fact, as long as an opening remains in the entire length of the canal as large as the bore of the lumbar puncture needle, no changes from the normal should be expected as long as the character of the wall, the viscosity of the fluid and the size of the opening remain constant.

It also explains why the dynamics are normal in a certain percentage of cases before cerebrospinal has been removed and why, when from 5 to 10 cc has been removed, the block first manifests itself as either a partial or complete obstruction. For instance, if the tumor is of such a size that it nearly fills the canal, the intraspinal pressure keeps an opening larger than the lumbar puncture needle. The removal of the fluid decreases the intraspinal pressure sufficiently to permit the dura and arachnoid to come in contact with the edges of the tumor and cord, thus producing block.

It should be emphasized, therefore, that a relatively large tumor may be present even though the dynamics are normal. If the patient's symptoms are suggestive of a spinal cord tumor, the cerebrospinal fluid dynamics are of real significance only when positive, and when

<sup>4</sup> Weed, L. H. Some Limitations of the Monroe-Kellie Hypothesis. Arch Surg 18: 1049 (April) 1929.

negative the introduction of iodized oil into the canal must be considered as the next best method of detecting a tumor, if it is at all possible. The diagnosis of spinal cord tumor should not be absolutely dismissed because the cerebrospinal fluid dynamics are normal

## PRESENT ENDOCRINE DIAGNOSIS AND THERAPY

### A CRITICAL ANALYSIS BASED ON HORMONE STUDIES IN THE FEMALE

ROBERT T FRANK, MD  
MORRIS A GOLDBERGER, MD  
AND  
FRANK SPIELMAN, MD  
NEW YORK

It is difficult to keep one's footing in a stampede and practically impossible to think or plan connectedly during a panic. Therefore, the members of the medical profession as well as the public, who have been caught in the whirlwind sweep of this new medical advance, have lost all sense of proportion, direction and balance whenever the subject of endocrinology is touched on. In spite of the turmoil, real progress can be recorded, often unheard, because of incoherent babble and ballyhoo, which is more vocal than constructive and conservative advances.

It has been our effort since 1925 to place the study of functional endocrine disturbances of the female sex organs on a more solid foundation and to devise methods that will permit evaluation of conditions comparable to metabolism determinations. Although our methods are now used in many laboratories throughout this country and abroad, the profession at large has not made use of these aids in diagnosis, prognosis and treatment to the extent that the information obtained by these technics appears to warrant.

The material on which our results are based, from January 1926 to December 1933, includes 1,773 estrogenic substance tests on blood performed in our laboratory, 1,269 urine tests for estrogenic substance, 661 anterior pituitary tests on the blood, 78 anterior pituitary-like tests on the urine, 1,843 tissues, cyst fluids, bile, cerebrospinal fluid and the like tested for estrogenic substance, and 916 pregnancy tests.

This large material which we have accumulated appears to warrant comprehensive publication. Perhaps it may help to clarify some of the confusion, loose reasoning and overenthusiasm that threatens further to obscure a very complex subject. Concrete data may serve in restoring balance and proper perspective.

In the spring of 1925 the presence of estrogenic substance was demonstrated in the circulation.<sup>1</sup> In the fall of the same year a clinical method for determining the presence of this hormone was devised.<sup>2</sup> In 1926, after Loewe<sup>3</sup> had demon-

strated the presence of the estrogenic substance in the urine, a method was published for determining its excretion in the urine.<sup>4</sup> In 1931 we<sup>5</sup> described a clinical quantitative test for the determination of the anterior pituitary hormone in the blood of nonpregnant women. Previously such determinations had been limited to the duration of pregnancy or the period after the menopause, at which times the anterior pituitary hormone values are sufficiently increased to permit testing without concentration.

### METHODS EMPLOYED

The details of our methods can readily be obtained from previous publication.<sup>6</sup> Two main hormone constituents have been studied, the one the estrogenic substance,<sup>7</sup> the other the anterior pituitary type of substance known as the gonadal stimulating hormone, gonadotropic hormone and closely related bodies, prol-an (Zondek) and pituitary-like hormone (Collip).

The estrogenic substance is concentrated by lipid extraction of the blood or urine. The blood tests represent weekly samples of vein blood, 40 cc being used.<sup>8</sup>

The urine studies which show the entire output of estrogenic substance in successive seventy-two hour specimens are obtained by continuous chloroform extraction. The test object for the estrogenic sub-

Fig 1—Vaginal spread of castrate mouse. A negative leukocytes. B positive spread from same mouse forty eight hours after injection of extract containing at least one mouse unit of estrogenic substance.

stance, irrespective of its source, is the castrated adult mouse. The smallest amount of extract that in forty-eight hours produces a characteristic change in the vaginal spread is recorded as a mouse unit (fig 1).

The anterior pituitary types of hormone are obtained by us with acid alcoholic extractions of the 40 cc of blood specimens previously freed from estrogenic substance. The anterior pituitary-like hormone is extracted from the seventy-two hour specimens of urine by means of either alcohol precipitation<sup>9</sup> or adsorption.<sup>10</sup>

The test animal for the prepituitary reaction is the immature noncastrated rat and the test is recorded in

6 Frank and Goldberger. Frank A, Frank Goldberger and Spielman. Frank R T and Goldberger M A. The Female Sex Hormone. VIII Simplification of Technic. J A M A 90 376 (Feb 4) 1928.

7 The term female sex hormone was employed by us in former papers in THE JOURNAL to designate the estrogenic principle found throughout the plant and animal kingdom.

8 It would be preferable if more frequent blood tests could be taken and each test titrated on several animals. To counteract the individual susceptibility of test mice the amount of blood extracted has been increased from 35 cc to 40 cc. Perhaps the Fluhrman test which is based on a mucifying action on the vaginal epithelium—if found identical with our methods—may prove of value.

rat units For this test the changes taking place after 100 hours in the ovarian follicle are evaluated (fig 2)

The pregnancy tests of Aschheim and Zondek<sup>11</sup> and Friedman<sup>12</sup> were employed unchanged just as these authors recommended

#### THE HORMONE CYCLE IN THE NORMAL FERTILE MENSTRUATING FEMALE

Such a remarkable congruence was found in two composite graphs of the blood, based respectively on two series of women, the first dating from our earlier work in 1925 to 1928,<sup>13</sup> and the second in another group from 1930 to 1933, that marked deviations from this standard type may be considered abnormal and of significance

In the normal menstruating fertile woman the 40 cc blood samples do not contain a full mouse unit until from seven days before the menses With the onset of bleeding, the blood level again decreases

The urine cycle for estrogenic substance is likewise characteristic About the tenth day and again about three days before the menstrual bleeding, increased excretion takes place The normal monthly total output is from 1,200 to 1,500 mouse units (fig 3)

An earnest warning must be given against short cut technics by which attempts to draw conclusions from single isolated tests are attempted The data thus obtained are valueless, as their interpretation depends on accidental variations (fig 3)

Fig 2—Sections of ovaries of immature rat A normal untreated animal primordial follicles B anterior pituitary reaction 100 hours after injections of extract containing at least one rat unit of prepituitary or anterior pituitary like extract The follicles are enlarged and cystic

In the blood there likewise is an anterior pituitary hormone cycle

Between the eighth and the tenth day, a full rat unit (R U) is present in the 40 cc blood specimen Before and after, smaller quantities are found (fig 3, broken line)

Although minor discrepancies have been noted here and there, our earlier conclusions, based on blood and urine studies, which lead us to divide functional disturbances of the genital tract into two large classes, those of underfunction and those of overfunction, have been confirmed more and more by the accumulation of larger groups of patients

#### PREPUBERTY AND PUBERTY

To what degree the ovaries function before puberty is of interest Our studies on the estrogenic substance before the onset of puberty are still quite fragmentary A titer of the excretion on a child, aged 3 years, menstruating cyclically since the age of 6 months, shows that there is cyclic excretion under these conditions<sup>14</sup>

<sup>11</sup> Aschheim Selmar and Zondek Bernhard Schwangerschafts diagnose aus dem Harn (durch Hormonnachweis) Klin Wchnschr 7 1404 (July 22) 1928

<sup>12</sup> Friedman, M H and Lapham M E A Simple Laboratory Procedure for the Diagnosis of Early Pregnancies Am J Obst. & Gynec 21 405 (March) 1931

<sup>13</sup> Frank R T The Female Sex Hormone Springfield Ill Charles C Thomas 1929

<sup>14</sup> Frank R T Premature Sexual Development in Children Due to Malignant Ovarian Tumors with Special Reference to Hormonal Studies and After Treatment Am J Dis Child 43 942 (April) 1932

Our studies on a small group of normal children between the ages of 4 and 13 years show that very little estrogenic substance is usually excreted before puberty, an amount readily accounted for by the alimentary intake (an ordinary potato contains, for example, 2 mouse units of estrogenic substance)

Of fifteen children, only two gave any positive reaction A 4 year old girl showed 1 mouse unit in 500 cc of urine, a 9 year old girl, 1 mouse unit in 250 cc

A child investigated for cyclic vomiting at the age of 12½ years showed cyclic but less excretion of estrogenic substance than that seen in the adult menstruating female but more than in younger children (725 mouse units) Two and one-half months later the first menstruation appeared in this patient, and since that time the cyclic vomiting, which had occurred every four to four and one-half weeks, has disappeared completely

#### THE UNDERFUNCTIONING OVARIES, STERILITY, AMENORRHEA (DYSMENORRHEA AND OLIGOMENORRHEA) AND THE MENOPAUSE

Unless the ovaries have been directly injured by local action, such as by x-rays, we ascribe underfunction, with few exceptions, to primary pituitary disturbances The gonads, in spite of their prime biologic importance, are subsidiary glands under the direct control of the anterior pituitary (adenohypophysis) and dependent on the prepituitary cycle (fig 3)

Patients with underfunction, clinically identical, with monotonous regularity, fall into three main groups, (1) subthreshold blood cycle, (2) acyclic blood but cyclic urine cycle, and (3) acyclic, in both blood and urine (fig 4)

With equal regularity, according to this hormone grouping, the prognosis in class 1 has proved encouraging, irrespective of the duration of the complaint (sterility, oligomenorrhea, amenorrhea), in class 2, doubtful, in class 3, bad

**Amenorrhea**—The three hormone types characteristic of amenorrheas and all underfunctions of the ovaries allow for many individual variations, which enhance the difficulties of prognosis and, consequently, the evaluation of treatment, as can be readily illustrated

A woman, aged 28, had been married three years and was sterile The menses had never been regular She showed many endocrine stigmas, including moderate hirsutism with male escutcheon, a clitoris five times the normal size, and a high symphysis The basal metabolism was plus 12, and roentgen examination of the sella was normal The sugar tolerance was normal The fourth blood specimen showed a strong accumulation of estrogenic substance The urinary excretion of this hormone was likewise normal (1,825 mouse units) Hence we predicted an impending menstruation, which actually took place five days later, to the great surprise of the patient

We have had a number of similar cases in which impending menstruation could be predicted by means of the blood studies—one after six years of amenorrhea and one after seven years Had any therapy been given this would have been hailed as miraculous in its effect by both patient and medical attendant In another patient a cyclic accumulation of estrogenic substance in the blood but a much smaller excretion of estrogenic substance in the urine (900 mouse units total) was noted (fig 4B) In this patient, aged 33, although the amenorrhea was five years in duration, an absolutely good prognosis was given, which the subsequent course fully justified

In sharp contrast with the two cases just described is one of primary amenorrhea in a girl, aged 20, who made a very

normal physical impression, in whom a hormone study extending over five weeks showed a minimal subthreshold quantity of accumulation of estrogenic substance in the blood and almost a total absence of excretion in the urine (125 mouse units total) In this case the prognosis was very bad

The symptoms complained of by these patients vary greatly In the younger group, primary amenorrhea brings the patient under observation if menstruation

has not occurred at the time that racial and familial expectancy lead one to anticipate it (from the fifteenth to the twentieth year) Other children become amenorrheic after a longer or shorter period of menstruation (secondary amenorrhea) Adults who have reached the age of from 20 to 35 without menstruation are less common

After marriage, the same or similar patients seek advice because of sterility Before hormone investigations are made, the potency of the husband and the absence of cervical and tubal infection as well as mechanical permeability of the tubular tract are determined At the same time amenorrhea may or may not be complained of

Dysmenorrhea appears with great frequency in the group of patients who are overworked, infantile, and often sterile

The secondary amenorrheas and sterilities are most often noted in

patients afflicted with obesity If the obesity is due to overeating, judicious dieting will afford prompt relief Pituitary obesity is resistant, thyroid insufficiency, which unfortunately is uncommon in these fat women, is most amenable to treatment Amenorrhea due to asthenia is found in systemic disease (tuberculosis), psychoses, or in the infrequent cases of Simmonds' disease and suprarenal insufficiency

Amenorrhea in Absence of Vagina Occasionally nature supplies a critical experiment Patients with absence of the vagina may be normal in feminine configuration, eunuchoid, or verging toward the masculine Our experience now covers seventeen cases, of which fourteen have been studied in detail<sup>15</sup> The hormone studies, with two exceptions, show a definite cycle, which enables us to state that twelve of these patients are feminine individuals Retention of blood in the

vestigial genital tract cannot occur because the uterus is solid and without endometrium When no sex cycle was noted, the sex of the patient remained undetermined

Figure 5 shows a twenty-one day blood cycle with a fairly normal amount of urinary excretion (1,040 mouse units) On the other hand the blood cycle may be absent, the excretion in the urine resembling that found in puberty bleeding, in one instance 4,600 mouse units was excreted during a period of thirty-three days, which is approximately three times the normal

In both of these cases we are able to state that functioning ovaries are present, in fact, it would seem that in the second case they are overfunctioning

However, from a study of the graphs of these twelve patients, it appears that when there is an accumulation of estrogenic substance in the blood, less is excreted in the urine Whether this implies a definite utilization of the hormone by the normal uterus is as yet an open question, nothing being known as to how the estrogenic substance or in fact any hormone acts or combines locally<sup>16</sup>

**The Menopause**—The symptoms of the menopause, irrespective of whether normal and spontaneous, or artificially induced by operation (hysterectomy, double oophorectomy, or combined hysterectomy and salpingo-oophorectomy), are usually identical, consisting subjectively of protean neurovascular disturbances If the patient is young and the ovaries, one or both, are left in situ, local atrophy of the introitus and vagina remains in abeyance

Hormonally, however, marked differences are found

**Normal Menopause** Figure 6 shows what is considered the most typical finding of a high anterior pituitary reaction of the blood, no demonstrable estrogenic substance is found in the blood or in the urine

This anterior pituitary overload in the blood is noted in less than 50 per cent of such patients Not infrequently, a year

Fig. 3—Hormone cycle (E S and A P) of normal fertile menstruating woman Above base line (O) record of blood specimens taken every seven days Black dots E S estrogenic substance (solid line) small circle A P anterior pituitary (broken line), above  $2\frac{1}{2}$  = positive below  $2\frac{1}{2}$  = negative 1 = less than 1 mouse unit in 40 cc of blood Below base line total excretion of estrogenic substance in urine Figures to the left show amount of mouse units Total excretion 1,500 mouse units of estrogenic substance Each block represents three days A B C to show that single blood and urine specimens are valueless and misleading

Fig. 4—Occurrence of estrogenic substance in the blood and urine of normal and amenorrheic women A normal B subthreshold C negative blood cycle positive urine cycle D acyclical

or more after the menopause estrogenic substance is still cyclically excreted. This is not surprising, since follicles may be found in senile ovaries

<sup>16</sup> The sole evidence that a local accumulation of hormone actually occurs is supplied by the menstrual blood While the circulating blood just before the time of menstruation contains 1 mouse unit to every 40 cc the blood seeping through the endometrium (menstrual) may contain as much as 1 mouse unit to 2 cc Blood drawn by cupping from the portio vaginalis during menstruation however contains only the same amount of hormone as that found at any given time in the general circulation

<sup>15</sup> Frank, R T and Goldberger M A The Female Sex Hormone A New Method of Determining Sex in the Presence of Malformation of the Genital Organs J A M A 87 554 (Aug 21) 1926

**Artificial Menopause** Figure 7 shows blood studies performed on a woman, aged 35, whose uterus was removed seventeen years previously. A definite blood cycle of estrogenic substance has continued. This is the longest persistence of ovarian function with absence of the uterus that we have had the opportunity to observe.

In older women only the uterus of whom has been removed, a blood cycle with scanty excretion in the urine is evidence of persistent but diminished ovarian function.

In other patients if the anterior pituitary factor in the blood is high and no blood or urinary excretion of estrogenic substance is found, the true physiologic menopause is shown to have taken place.

Removal of the uterus need not abolish the blood and urinary cycle for anterior pituitary and estrogenic substance. From these examples of studies on both the natural and the artificial menopause it should be clear that, although the symptoms complained of may be identical, the humoral conditions may differ widely in different individuals. This, too, may explain the great divergence in response to therapy noted in different women.

**Vicarious Menstruation—Molimina**—Considerable prominence has been given to "vicarious" menstruation. A study of patients with primary amenorrhea suffering with "cyclic" epistaxis showed no blood or urinary cycle. In the blood sickening from the nose, no estrogenic substance could be demonstrated. In our experience, no case of true vicarious menstruation has been observed.

In sharp contrast to this, "molimina" in amenorrheic patients, such as engorgement of the breasts, pelvic heaviness and periodic leukorrhea, may signify cyclic ovarian function, as shown in figure 8.

#### OVERFUNCTION OF THE OVARIES. PUBERTY BLEEDING, MATURITY MENORRHAGIA AND METRORRHAGIA, PRECLIMACTERIC HEMORRHAGES (PREMENSTRUAL TENSION)

Again, as in the preceding group, disturbance of the anterior pituitary must be regarded as the etiologic factor.

From our studies it has become apparent that the blood hormone level for estrogenic substance is a most

Fig. 5—Absent vagina. Twenty one day blood cycle. normal urine cycle.

delicately balanced mechanism in which the normal by our method of extraction is approximately 1 mouse unit to 40 cc of blood, or 25 mouse units per liter. Only after the eighth week of pregnancy is this level exceeded, at which time not more than twice this amount normally accumulates in the blood (50 mouse units per liter).

This high level also occurs in a small group of cases which we designate as "premenstrual tension." No such increase develops when huge doses of estrogenic substance are injected

intravenously or even when a great excess is spontaneously produced, as in suprarenal tumors.<sup>17</sup>

And yet, without exceeding the higher physiologic limit, the same amount of estrogenic substance, depending on the rapidity or failure of excretion, may and does produce the differences illustrated in figure 14. This difference in effect is due to differences in the level of excretion, which varies greatly in different individuals and as we have previously stated,<sup>18</sup> may also vary at different times of the cycle in the same individual. This variation in excretory threshold is

Fig. 6—Natural menopause in a woman aged 53. High anterior pituitary reaction. No blood or urine cycle.

probably directly influenced by the pituitary secretion, which is cyclic in the normal female (fig. 3, broken line).

The symptoms of ovarian overfunction in the majority of instances are excessive and irregular bleeding—menorrhagia and metrorrhagia. In the "tension" cases, mentioned before, bleeding is normal. In suprarenal tumors, amenorrhea predominates. If the blood hormone level is persistently high and no cyclic excretion of estrogenic substance occurs through the urine, amenorrhea should result.<sup>19</sup>

Excessive bleeding, we have found, as a rule, bespeaks overfunction of the ovaries because, almost without exception, these bleeding cases show a markedly excessive excretion of estrogenic substance in the urine, although the amount recoverable from the circulating blood may actually be diminished.

In our large material, only three exceptions to this rule so far have been noted, both in patients with diminished thyroid function and in obesity (relieved by thyroid extract).

Menstrual bleeding in its simplest form, although this does not correspond to the true physiologic menstrual process, can be experimentally induced in castrated primates by the continued injection of large amounts of estrogenic substance. Bleeding does not occur if the proper hormone level is maintained until the injections are stopped (in the macaque<sup>19</sup> and in man<sup>20</sup>).

The prerequisites for normal menstruation, on the other hand, are more complicated. They consist in preliminary preparation of the uterus by estrogenic substance and then sensitization by the special corpus luteum hormone (progesterin). Unless these two factors act in succession on the uterus, nidation is impossible.

"Anovular" menstruation has been much featured in the recent literature, consisting in ripening of the follicles, with consequent production of estrogenic substance, but without

<sup>17</sup> Unpublished data.

ovulation or formation of the corpus luteum<sup>21</sup> This type of disturbance is said to produce both cyclic menstruation and irregular bleeding Clinically, it is best exemplified by the usually transitory condition known as "polycystic or microcystic ovaries"

Our studies of cyst fluids are interesting in this connection Follicle cysts of all sizes, if lined by granulosa cells, contain estrogenic substance in considerable concentration Simple "serous" cysts give no estrual reaction, nor is any effect produced by pseudomucin or dermoid cyst fluid

On the other hand, polycystic ovaries may likewise cause amenorrhea if the blood hormone level for estrogenic substance remains continuously high This produces chronic hyperplasia of the endometrium, amenorrhea, and an excessive continuous excretion in the urine of the estrogenic substance—the "polyhormone amenorrhea" of Zondek and others—"amenorrhea of overfunction" Our observations lead us to consider this group much less numerous than was at first believed

In marked contradistinction to the hormone conditions found in functional bleeding, the irregular uterine bleedings due to inflammation (tubal, peritubal, cellular exudates), tumors of the uterus (including small submucous fibroids) show either a normal or a subnormal amount of estrogenic substance excreted through the urine, thus affording a characteristic differential, useful in diagnosis

The following groups illustrate overfunction

**Puberty Bleeding**—This constitutes a fairly numerous group between the ages of 10 and 20 years

Figure 9 charts the bleeding of a girl, now 17 years old, watched for five years during which time curettement was done three times (hyperplastic endometrium) and transfusion four times (hemoglobin down to 30 per cent on one occasion) No blood studies were made, repeated urine studies showed typical overexcretion

The menstrual blood in these cases contains much estrogenic substance, as high as 500 mouse units per liter for days and weeks

**Adult Menorrhagia and Metrorrhagias**—This large group is most often encountered by the physician In the early stages the patient's uterus is normal The uterus eventually, in the course of years, enlarges symmetrically (at first boggy, later firm and fibrous) Curettings show hyperplastic, polypoid or cystic endometrium The ovaries are normal or may be "microcystic"

A woman, aged 23, married for five years, had had an abortion five years before She started to menstruate at 13

Fig 7—Induced menopause Hysterectomy seventeen years previously at age of 17 years Cyclic ovarian function has persisted seventeen years

years and bled excessively every two weeks She had had radium treatments at another hospital The blood studies (fig 10) showed a fifteen day blood cycle excretion in thirty-three days 4185 mouse units (normal 1,500 mouse units) Six months later she became pregnant with a normal termination, good evidence that such conditions are functional and often self limited

Figure 11 shows one cycle in a woman, aged 31 who had had an ovarian cyst removed five years previously The menorrhagia had existed for two years After the blood

studies were completed, bleeding became and has remained normal without treatment The studies extend over two four and one-half week periods (only one of which is shown) In both an occasional, but not cyclic, accumulation of estrogenic substance in the blood was noted In both a marked excess of estrogenic substance was excreted 6,000 mouse units and 7,425 mouse units (normal 1,500 mouse units)

In sharp contrast to these typical cases and charts are two examples of organic disease, the first from a patient whose bleeding was due to small submucous fibroids, the other suffering from subacute adnexal

Fig 8—Amenorrhea molimina Arrow indicates time of breast engorgement and pelvic pain Blood cycle occurs

inflammation (figs 12 and 13) In both it will be noted that the ovarian function is low

**Preclimactic Bleeding**—This shows the same changes as in puberty bleeding and appears to be due to the same functional causation

**Premenstrual Tension** (overfunction without excessive bleeding)<sup>22</sup>—In this carefully studied group, characteristic psychic and physical symptoms develop increasingly from the second week on until the onset of menstruation Within one to six hours after the flow begins, complete relief is experienced

An illustrative case in a woman, aged 40, showed psychic instability and unrest, she stated that she felt like jumping out of her skin Physically there were tense breasts, edema of the ankles, and pelvic engorgement

Figure 14 shows the typical marked progressive increase of estrogenic substance in the blood (first week 40 cc gives 2 plus reaction, second week 40 cc gives 4, third week 30 cc gives 4, fourth week 20 cc gives 4 In the normal female 40 cc gives 0 until the fourth week, then 40 cc gives 4)

In marked contrast to the blood curve, the urinary threshold in these women is high, only from 250 to 350 mouse units being excreted during a cycle (normal 1,500 mouse units)

This condition exemplifies the strong effect produced by comparatively small amounts of hormone if excretion, and perhaps also utilization or destruction, is defective

#### PREGNANCY CONDITIONS

Because of limitations of space, hormone studies in normal and abnormal pregnancy, as well as in chorion-epithelioma in the male, will be reserved for later publication

#### DIAGNOSIS

In the preceding we have given a brief review of the results derived from our hormone studies The information obtained from hormone graphs on ovarian function have thrown light on symptoms and diagnosis as well as on the reason for success or failure of the therapy However, such studies, though they serve as valuable aids, cannot replace clinical acumen and experience

The general impression made by a patient on an experienced observer is of much importance It is essential to have the patient strip in order not to be deceived by artificial and adventitious aids On the one

<sup>21</sup> Schroeder Robert Arch f Gynak 110 63 1919 Geit S H Abence of Corpora Lutea in a Case of Atypical Uterine Hemorrhage J A M A 78 1185 (April 22) 1922

<sup>22</sup> Frank R T The Hormonal Causes of Premenstrual Tension Arch Neurol & Psychiat 26 1053 (Nov) 1931

land, it is surprising to see how those not specially trained will overlook marked evidence of serious endocrine disturbances and, on the other hand, ascribe to endocrine causes symptoms clearly due to local diseases

R M was a most peculiar looking individual, definitely acromegalic, with hirsutism, exophthalmos, the clitoris six

Fig 9—Puberty bleeding overfunction shown by excessive excretion of estrogenic substance (5330 mouse units in black). The stippling shows amount excreted by a normal woman and superimposed as a contrast

times the normal size the labia resembling a split scrotum a funnel-shaped introitus and brandlike high fourchette. In spite of these well marked stigmas of external pseudohermaphroditism and of serious general endocrine disturbance the patient was cured and later had her ovaries resected for menorrhagia. A year later insufflation tests were performed because she had not conceived

To avoid gross mistakes of this kind, it is essential to train the eye to recognize the various types that may still be considered normal, although they may merge into those suffering from actual endocrine disease

A nontechnical classification is as follows

Normal feminine

Infantile with excessive trunk length

Eunuchoid with excessive extremity length

Masculine, harsh voiced phlethoric, hirsute

Acromegaloid

Thyroid ( $\pm$ ), myxedemoid ( $-$ ), basedoid ( $+$ )

In order not to be misled, we try to obtain photographs of the patient at various ages and, whenever possible, compare the given individual with other members of the family for nature permits itself wide variations in type, both racial and familial. In this way a tall individual coming from a tall family would not *co ipso* be classified as eunuchoid or a short thick-set individual in whom all the members of the family show similar traits without symptoms will not, offhand, be classified as a Froehlich type of individual

In seeing a large number of patients suspected of endocrine disturbance, the experienced diagnostician will not find it necessary to subject every individual to a complete workup. In what appears to be a mild transient disturbance, whether menorrhagia, amenorrhea, sterility after short periods of marriage or the like, often merely a thorough physical examination is given and further study is postponed in the hope that spontaneous rectification will take place during observation

Whenever the duration of the disease, however, has been longer or when real endocrine stigmas are noted, certainly in any endocrine clinic, more detailed studies must be undertaken. In the main these consist of complete physical examination, blood count including differential count, anthropometric measurements, basal metabolic tests, a roentgen examination of the sella turcica, fundus and visual field examination, and always in obesity cases a sugar tolerance test (Janney)

After these data have been obtained we decide whether a hormone test extending over an entire cycle or, if the patient is amenorrheic, over a period of five weeks, is indicated

The roentgenogram of the sella has been particularly useful. During the course of each year we pick up several silent pituitary neoplasms which usually mask under the guise of an innocent amenorrhea or obesity, not infrequently a combination of the two

E W, a woman, aged 22, had had amenorrhea for five years. A roentgenogram of the sella showed an enlarged floor and marked thinning out of the sphenoid. At operation a pituitary tumor was removed

E S, a woman aged 23, had one child nine months before and had been bleeding excessively since. The patient was 5 feet 4½ inches (164 cm) tall and weighed 223 pounds (100.7 kg). A hormone study was made in which no blood cycle was noted and only 405 mouse units of estrogenic substance was excreted in the urine (one third of the normal). A previous sellar roentgenogram showed a very large sella. There was some blurring of the right ocular disk although vision was not yet impaired. Perimetric examination showed concentric diminution of the visual fields

The patient was then lost sight of. I have since learned that she has had a resection of the ovaries performed for the bleeding at another institution where apparently no attention was paid to the serious endocrine changes, which will eventu-

Fig 10—Menorrhagia fifteen day blood cycle excessive excretion (4185 mouse units). Stippled area shows uterine bleeding

ally lead to typical cerebral symptoms of pituitary tumor from which this patient suffers

**Basal Metabolism**—We always hope, in cases of obesity, to find a diminished basal metabolism. This hope is, however, rarely fulfilled, as the majority of obese patients show a normal metabolic rate and many of them do not tolerate thyroid in any form

In underweight asthenic patients, the basal metabolism is frequently found below normal, at times running as low as minus 20. Our experience has been that in many of these patients, by increasing the protein factor of the diet, the metabolic rate may be restored to normal. Before resorting to thyroid medication, we prescribe this dietary change.

**Blood Examinations**—Whenever in adult patients there is a permanent increase in the lymphocytes this is considered an indication of real endocrine disturbance. This increase, which may reach a total of from 40 to 60 per cent, is found quite regularly in thyroid disturbances of both overfunctional and underfunctional types, occasionally in acromegaly and not infrequently in obesity. While not helpful in actual diagnosis it is usually a warning that a real endocrine malady is present.

**Sugar Tolerance**—In all cases of obesity that do not respond to diet, it is our custom to perform a Janney test after the patient has been on a reduced carbohydrate diet for at least a week. Persistence of a high sugar level in the blood without appearance of sugar in the urine, regularly bespeaks an obesity that will not respond readily to the ordinary dietary measures.

Fig. 11—Menorrhagia Cycle showing marked overexcretion (7425 mouse units)

# TREATMENT

Our hormone studies were undertaken in the hope not only of learning more about the nature of the various diseases studied but also with the expectation that these studies might prove useful in the devising of successful therapeutic measures. Our expectations have been realized only to the extent of preventing self-deception as to our therapeutic results and throwing much light on the self-limitation of many endocrine disturbances with spontaneous cure. The following dramatic cases will throw some further light on these statements.

R B, a woman aged 22 whose marriage had been sterile for three years had periods of amenorrhea for from six to three months. The patient was of the infantile type. She was 4 feet 11 inches (150 cm) tall and weighed 93 pounds (42.2 kg) normal 113 pounds (51.3 kg). The basal metabolism was minus 2 per cent. The blood pressure was 120 systolic, 98 diastolic. The Janney test showed a high sugar tolerance. Sellar roentgenograms were normal. The blood was normal. During a period of amenorrhea there was no accumulation of estrogenic substance in the blood. A urine test was not performed as this was in 1929. The patient was observed for the next two and one half years without any treatment. Menstruation has become normal and she has given birth to a normal child.

J F, a girl aged 17½ years, had never menstruated. Her sister menstruated at the age of 12. There was a slight indication of eunuchoidism. The basal metabolism was minus 12 per cent. The patient was distinctly overweight. After three months' observation, menstruation set in and has remained normal.

A R, a girl, aged 15 years, referred to us because of a possible basophilic adenoma, was markedly overweight. There was definite prognathism. The shoulders were heavy. There

Fig. 12—Menometrorrhagia due to fibroids. No sign of ovarian overfunction.

was a slight dorsocervical kyphosis. There was diffuse sparse hirsutism and escutcheon. The sella turcica was normal. There were moderate striae on the abdomen. The sugar tolerance was normal. There was early closure of the epiphyses (like 18 years). The basal metabolism was minus 3 per cent. No treatment was given except reduction in weight. After 30 pounds (13.6 kg) was lost, normal menstruation began and has continued.

E H, a woman aged 29, unmarried, had had menses since she was 13½ years old. Amenorrhea had been present for one year. There was hirsutism. The blood count was normal. The basal metabolism was minus 8 per cent. The genital tract, the sella turcica and the weight were normal. The patient bled after the first interview and has continued to menstruate since then.

E M, a girl aged 15½ years, has eight normal sisters and brothers. She has frequent temporal headaches. The patient was 4 feet 7 inches (139.7 cm) tall and weighed 66 pounds (29.9 kg), normal 110 pounds (49.9 kg). There was no axillary hair, and only a few sparse pubic hairs. The breast development was that of a girl from 5 to 6 years of age. The uterus was extremely small. The basal metabolism was plus 19 and plus 38. Roentgenograms of the sella were negative and of the long bones showed no delay of development or epiphyseal union. The patient was put on increased nourishment and began to menstruate normally after five months.

R L, married, had had amenorrhea and been sterile for five years. When first seen she was found three months pregnant and was delivered at term.

Fig. 13—Menorrhagia and metrorrhagia due to pelvic inflammation. No sign of ovarian overfunction.

L P, aged 32, had one child, aged 17 years. The patient was obese and showed hirsutism, general and of the face. She had had amenorrhea for one year. The basal metabolism was minus 12. The sugar tolerance and blood count were normal. She was abdominous and had short arms and legs.

The patient received various estrogenic substances during 1927. During 1928 she lost considerable weight but the long periods of amenorrhea continued. In 1931 she became pregnant and was delivered of a full term child in August 1932. She was delivered of another child in October 1933.

These few cases, selected out of many, illustrate the spontaneous recovery from obscure endocrine conditions, which in some of these patients appeared grave. We must again emphasize that, had any medication been given, these spontaneous cures would have been ascribed to the treatment. This type of case should act as a full reply to the numerous questions put to us as to how to explain almost miraculous results from various treatments in isolated cases, because every physician encounters surprising response to "therapy" in isolated instances. Unless one is extremely critical, the results so often accidental are regularly ascribed to the therapy.

In marked contrast to the foregoing, a few cases in which futile attempts at therapy were practiced are worth quoting. Some were based on carelessness and incompleteness of diagnosis. Others may be ascribed to the extreme optimism shown by many physicians.

M. C., aged 31, had been subjected to supravaginal hysterectomy for fibroids. This rather stupid patient consulted a physician, who found out that she no longer menstruated and thereupon gave her a long series of injections of Amniotin in the form of estrogenic substance, to bring back the menses."

Fig 14—Contrasting premenstrual tension and normal function. Normal estrogenic substance in blood shown by solid line. Tension estrogenic substance in broken line. Tension shows increased estrogenic substance in blood. Decreased excretion 300 mouse units (solid blocks) compared to that of normal female (1500 mouse units).

A young woman aged 20 came to our endocrine clinic complaining of primary amenorrhea. She had been given a long course of anterior pituitary-like principle from the urine of pregnancy and theelin by various private physicians without result. Pelvic examination showed absence of the vagina.

A. B., aged 29, unmarried, complained of increase in weight and amenorrhea for the last eight months. She had been treated for obesity by diet and dimetrophenol, and had also been given thyroid extract. On examination this patient was found seven months pregnant.

Let these few cases suffice in showing to what extent "hormone therapy" is practiced without proper criteria.

#### "ESTROGENIC" SUBSTANCES

**Endocrine Remedies**—Needless to say, we have tested out both in the laboratory and in the clinic the usual endocrine products as they become available. Until quite recently all the remedies taken by mouth contained no active principle whatever.

Within the last few years, the estrogenic substance in considerable concentration has become available in tablet form, as for example Progynon tablets, or in pessaries for vaginal absorption, in Amniotin pessaries.

For hypodermic injection, the estrogenic substance is dispensed under the name of theelin, Amniotin, Progynon, Menformon, and the like, and can be obtained in strengths varying from 150 to 1,000 mouse units per cubic centimeter, in remarkably pure form. Such a preparation certainly appears attractive. In our clinic it has been used on considerable groups of patients for amenorrhea, oligomenorrhea, excessive bleeding and the symptoms of the menopause. In none of these conditions have we found it of real and convincing value.

Our studies on animals have shown that when as much as 20,000 mouse units of estrogenic substance is injected into the circulation of a castrated rabbit, the hormone disappears from the circulation within half an hour. When such an animal is killed twenty-four hours later and its tissues are completely extracted, barely a trace of estrogenic substance can be recovered.

In two instances, female volunteers submitted to the injection of large doses of estrogenic substance. One was a fertile menstruating woman in whom no increase of excretion could be noted during a month, although the injections were spaced at weekly intervals. In the other, a markedly asthenic young woman amenorrheic for two years about one fifth of the total injected dose (40,000 mouse units) was eventually recovered from the urine.

Our clinical and animal results are discouraging. We feel confident that to produce an actual menstruation in the castrated human female will require the 250,000 mouse units that Clauberg<sup>20</sup> found necessary to employ and then that no benefit will accrue to the patient.

Were we inclined to use this therapy in functional amenorrhea after serious endocrine diseases such as pituitary tumors had been excluded we would give a total of 15,000 mouse units divided in three doses, injected every other day during one week. These injections would then be repeated at intervals of five to six and seven weeks, in the hope thus to strike a time at which follicular growth was actually occurring and the therapy prove an adjunct to the normal but subthreshold cycle. However, it should be kept in mind that conclusive experiments have shown<sup>21</sup> that continued high dosage of estrogenic substance has a distinctly sclerosing effect on the ovaries. The permanence of this unwished for effect has as yet not been fully determined.

We agree fully, therefore, with the opinion expressed in the admirable summary issued by the Council on Pharmacy and Chemistry.<sup>21</sup>

**Anterior Pituitary Hormone**—The true anterior pituitary hormone has not as yet been isolated in such a form as to be available for therapeutic use.

As a substitute, the anterior pituitary-like hormone obtained from the urine of pregnant women and dispensed under the form of Antuitrin-S, Follutein, Prolan, and the like has been extensively employed.

Laboratory investigation has shown that the anterior pituitary-like hormone (it is denominated prepituitary-like because in the absence of the pituitary in the test animal the prepituitary-like hormone does not exert a full effect) produces ovulation and corpus luteum formation, particularly in rodents. Unfortunately, as the studies of Geist<sup>22</sup> have shown, the effects on the human being are distinctly different, even when huge doses are given. This investigator found that in the human being some interstitial bleeding into the ovarian stroma and some increase in theca cell luteinization took place. Just what physiologic effects are produced by this change, he was as yet unable to determine. Clinically no effect could be noted.

<sup>25</sup> Geist S. H. Reaction of the Mature Human Ovary to Antuitrin S. *Am. J. Obst. & Gynec.* 26: 588 (Oct.) 1933.

Although much lauded in the literature (Novak and others), our own experience with prepituitary-like hormone has been unsuccessful in functional bleedings. This is readily understood when we are once aware that the expected corpus luteum formation, which at best should not produce more than what is called "dumb rut" in animals, does not result.

Various other endocrine constituents have been tried by us in gynecologic diseases. Our experiences with insulin and parathyroid extract have been quite unconvincing and have been discontinued.

#### RECOMMENDED METHODS OF TREATMENT

**Underfunctioning Ovaries**—Those amenorrheas due to obesity, asthenia or depressed thyroid function usually respond promptly to treatment. The obesities require strict limitation of carbohydrates and fats, with a sufficient amount of protein to keep up strength and energy. We recommend slow but continuous loss of weight, at the rate of 1 pound a week, until the normal weight has been reached.

Such a diet requires minute instruction, a detailed dietary and occasional encouragement at personal interviews. The asthenic patients, a less numerous group likewise require stressing of the protein factor of the diet but in addition sufficient carbohydrates and fats. The patients whose thyroid function is definitely reduced (minus 15 or lower) usually respond very promptly to thyroid medication. We find no advantage in giving thyroxine, usually employing the desiccated thyroid substance. Every eight to twelve weeks a basal metabolism test should be taken.

With the exception of these three types of patients, our therapy in amenorrhea as well as in sterility has not shown the slightest results. We exclude deliberately the spontaneous recoveries that are so frequently accepted as therapeutic triumphs.

It is quite possible that the amenorrheas and sterilities due to underfunction of the ovaries may respond to anterior pituitary medication when this becomes available. The giving of "estrogenic" substances appears entirely illusory and at best even in the highest dosage could bring about only a single anovular "menstruation."

Dysmenorrheic patients are best relieved by putting them into good condition. This applies especially to the asthenic group.

In addition a combination of small doses of codeine with coal tars, as for example codeine, one-fourth grain (0.016 Gm.), amidopyrine, acetphenetidin and acetylsalicylic acid, 2 grains (0.13 Gm.) of each, may be repeatedly given during the time that pain is felt. At the same time one or more doses of  $\frac{1}{500}$  grain (0.0003 Gm.) of atropine may be given by mouth until dryness of the throat is noted. None of the many other methods of treatment recommended, such as operations on the cervix (Dudley, Pozzi, Blair Bell), nor the many antispasmodics lauded for these complaints have shown any effect. Occasional dilation without curettage, gives temporary relief over the next few succeeding periods. Twice in the experience of the senior author has it been necessary to induce permanent amenorrhea (once many years ago by double oophorectomy, once by roentgen sterilization) because of the incapacitating suffering. Morphine should never be given to these patients.

**The Menopause**—From our hormone studies we realize that the menopause even when the symptoms are like men show entirely different humoral conditions. None of the recommended endocrine preparations either estrogenic or gonadotropic have proved effective. Reassurance, long continued use of mild sedatives such as bromides and phenobarbital, hot alcohol rubs and occasional small doses of ergot, from 3

to 5 drops three times a day for two or three days, intermitted for a week, have shown the most satisfactory effect.

**Overfunction of the Ovaries**—Premature puberty, if due to so-called essential causes, requires no treatment. When it results from ovarian tumors, these must be removed. We have encountered no premature sexual maturity due to pineal growths.

The puberty bleedings require long-continued care. When first seen in a condition of marked anemia (hemoglobin from 25 to 30 per cent) transfusion is indicated. Today chief reliance is placed on the moccasin venom treatment devised by Peck,<sup>26</sup> which, if long continued, regularly controls these bleedings. Occasionally curettage, in order to give temporary relief of the bleeding, may have to be practiced. After these patients reach the sixteenth, seventeenth or twentieth year, they one and all become normal.

**The Functional Bleedings of Maturity**—It is important first to rule out organic lesions, which is not always easy. The gonadotropic hormones, frequently lauded for these complaints, in our hands have proved ineffective, which, considering the fact that if active they should further stimulate the already overacting ovaries, is not surprising. These patients require treatment along strictly gynecologic lines.

In the milder troubles, bed rest, ice bags or short hot douches may be tried. Next, thorough curettage is indicated. If this brings only temporary relief, we have repeatedly, even during the child-bearing age, reduced the functioning of the ovaries with carefully applied x-rays, which in the hands of the expert can be accurately graduated to produce reduction of bleeding, oligomenorrhea or amenorrhea as desired, in women below 35 years of age. A number of these women have later borne normal children.

The preclimacteric bleedings that appear on the same basis as the puberty bleedings, namely, overfunction, should be treated by curettage, and, as these patients are approaching the menopause, no hesitation need be felt in using sterilizing doses of x-rays.

**Premenstrual Tension**—In this comparatively small but clear-cut group, relief can be obtained by giving a saline cathartic a week or more before the anticipated menses, at the time that the "tension" is most annoying. After, for example, a bottle of magnesium citrate is taken, no fluids must be ingested until the bowels have moved freely at least twice. Then for the next few hours the patient should drink large quantities of water, tea or coffee. A surprising degree of well being results from this simple treatment.

#### SUMMARY

Quantitative hormone studies show the humoral status before and at puberty, during maturity and after the menopause.

Functional genital disturbances are of two types—underfunction and overfunction.

Both types are primarily due to disturbances of the anterior pituitary cycle, the ovarian cycle being secondarily affected.

Emphasis is placed on the accurate "size up" of the individual studied and on other laboratory aids which help in the recognition and evaluation of congenital and acquired endocrine stigmas.

## A NEW TREATMENT OF TRAUMATIC DERMAL MYIASIS

M. A. STEWART, PH.D.

AND

A. N. BOYD, M.D.

HOUSTON, TEXAS

Myiasis is defined as the invasion of any part of the body of man or animals by dipterous larvae (fly maggots). Traumatic dermal myiasis is the invasion of wounds or ulcers of the skin by these larvae. Maggots invading skin wounds and ulcers will also penetrate into the underlying exposed tissues. The presence of these organisms accentuates the putrid condition of the sores and the suffering of the patient and, not infrequently, considerable quantities of tissue may be destroyed by their feeding activities.

One of the earliest published references to traumatic dermal myiasis was that of Joseph<sup>1</sup> in 1800, and a large number of similar observations have been published since then, especially by medical practitioners and investigators in the warmer regions of the globe. Traumatic dermal myiasis is of common occurrence in the southern part of the United States. However, entirely too often it is not accurately diagnosed, especially when the maggots are deeply embedded. When it is noticed frequently only a small number of larvae, those on or close to the surface, are removed, the others remaining undiscovered and thereby escaping treatment and subsequent removal.

Usually the treatment of this type of myiasis is very briefly described in medical textbooks with the information that the infested wounds are treated with antiseptic douches, the larvae being subsequently removed with appropriate instruments after which an antiseptic dressing is applied. Actually, a number of different treatments for this condition are widely used. One of the most highly recommended of them, and the one that has been the most satisfactory thus far, is irrigation of the wound with 20 per cent chloroform in sweet cow's milk. The fat in the milk tends to stifle the embedded larvae, which consequently attempt to leave the wound and in so doing are killed by the chloroform. They are then removed with forceps and the wound is dressed with an antiseptic dressing. Some of the other more commonly used methods of treatment are surgical removal of the maggots, and douching or irrigating the infested wound with chloroform, benzene, infusion of pyrethrum, turpentine, 2 per cent phenol (carbolic acid) infusion of basil (*Ocimum basilic*) and even salt water. Following such irrigations the wound is washed with luke warm water and an antiseptic dressing is applied.

A year and a half ago, during our term of service in the orthopedic division of the Jefferson Davis Hospital of Houston, Texas, cases of traumatic dermal myiasis were seen from time to time, and being dissatisfied with the milk-chloroform treatment, because

the preparation had to be made up fresh for each treatment and because from two to four treatments were usually necessary for each case, we made an attempt to find some more satisfactory method.

In the search for a new douche the following requirements were kept in mind: a substance that would cause the maggots to leave the deeper portions of the wound and that would kill them before they could completely escape, a substance that could be made up in quantity and would remain stable over a considerable period of time, and a substance that would have a soothing effect on the wound.

After considerable experimentation a satisfactory diluent, or vehicle, for the chloroform was found in light vegetable oil, any light oil of vegetable origin seems to be equally effective. In this substance the chloroform is entirely soluble, whereas in milk it is practically insoluble. Milk contains about 87 per cent water, and chloroform is so slightly soluble in water that only 0.66 Gm. will dissolve in 100 cc. of water at 22 C. If kept in a closed container, the chloroform-vegetable oil solution will keep indefinitely. When applied to a wound, the oil in the solution has a very soothing effect on the raw tissue. Owing to the solubility of chloroform in vegetable oil, only 15 per cent chloroform need be added to the diluent instead of 20 per cent, as when milk is employed in this capacity.

Seventeen cases of traumatic dermal myiasis have been treated with this mixture in the following way. When the infestation is on an extremity so that the entire part can be submerged in a vessel containing the chloroform-vegetable oil solution, this is done for thirty minutes, but when such a procedure is not possible the wound is kept flooded with the substance for the same length of time. In the latter event such flooding can be facilitated by first douching the cavity of the wound and then placing a flat gauze dressing over the wound and keeping it saturated with the douche. At the end of thirty minutes the dead maggots can be picked off the surface of the wound or out of the flat dressing, as the case may be, and the wound is dressed with a sterile bandage. In every case tested, all the larvae were removed from the wound in a single treatment, which is rarely the case when chloroform and sweet milk are used. In thirteen of these cases so treated, maggots were reared and the adults were identified as Texas screw-worm flies (*Cochliomyia macellaria* Fabr.).

This method has been employed to remove "surgical maggots" that have been placed in osteomyelitis for therapeutic purposes, with equally good results.

### SUMMARY

A new douche, composed of 15 per cent chloroform in light vegetable oil, has been employed in the treatment of seventeen cases of traumatic dermal myiasis. In every case all the maggots were removed with a single treatment, extending over a period of thirty minutes, such results are very rare when 20 per cent chloroform in sweet cow's milk is used.

The new douche has further advantages over the commonly used chloroform-milk solution in that chloroform is entirely soluble in vegetable oil and only slightly soluble in milk, in that the chloroform-vegetable oil solution is very stable and can be kept indefinitely in closed containers, whereas the chloroform-milk mixture has to be made up fresh for each application, and in that the vegetable oil is very soothing to the raw tissue of the infested wound.

## ADOPTION PRACTICES AND THE PHYSICIAN

R L JENKINS, M D  
CHICAGO

In this article adoption is considered in its purely human aspects as it concerns the medical profession. The relation of adoption to legal inheritance is beyond its province.

It is generally conceded that there is no social institution that can be regarded as an adequate substitute for the home in the training and socialization of children. There was a time when the inability of parents to support their children was considered a sufficient reason for the placement of the children outside the home. What such a policy would mean during the present crisis of unemployment must be apparent to all. There is a general agreement at present that, in instances in which it is necessary, children are best safeguarded by the conservation of the home through relief or social case work, with the exception of that small minority of instances in which the home is unfit.

There are certain children whose parents are dead, insane, feeble-minded, invalided, or otherwise unfit or unavailable for whom this solution is impossible. There is also the problem of the children of illegitimate unions and the community attitude which stigmatizes the unmarried mother and the bastard child. In the instances in which for certain reasons a child's own home is unavailable for its nurture, the first consideration should be the possibility of substituting another family home for the one it has lost.

Haste in the separation of an illegitimate child from its mother is rarely a virtue. In the pressure and turmoil following the birth of an illegitimate child an unmarried mother may give consent to its adoption and may deeply regret her consent a year or two later when she may be in a position to care for the child. The careful mustering of available resources during the pregnancy may prevent precipitate and probably permanent separation of the mother and child. Immediately after the birth of an illegitimate child the barriers to the care of the child within the family may seem unmeasurably high to the mother, yet the solution may not be difficult later.

The interest of the child and of the community (the two are commonly identical) should be considered paramount in the placement of children for adoption. The interests of the adoptive parents and of the original parents, while worthy of consideration, are secondary to these. The problem of placement for adoption is the problem of the selection of the most suitable home available for a given child.

The problems of adoption practice are so interwoven that they do not readily lend themselves to formally organized discussion. In this paper an attempt will be made to consider the adoption procedure under the headings "Investigation of the Home," "Investigation of the Child," "Individualization of Placement," and "The Probationary Period." Some overlapping of discussion can scarcely be avoided.

### INVESTIGATION OF THE HOME

The responsibility involved in placing a child in an adoptive home is a grave one. The child is defenseless, and the power of the adoptive parents is almost

unrestricted. The placement will determine the future course of the life of the child.

The adoption of a child, like other human acts, proceeds from a motive. The motive at times may be but dimly recognized by the prospective parents. Children are adopted to fill a need or to serve a purpose in the lives of those who adopt them. In judging the suitability of prospective adoptive parents, an estimate of the motive for desiring a child is essential. An attempt should be made to judge the probable effect on the child of the emotional attitudes indicated by this motive. Sometimes the adoption of a child is sought from a motive that is grossly improper, as in the following.

The widow of a wealthy man, in order to receive a large share of his estate, secured a child and pretended that it was the posthumous child of her deceased husband. Another case found during the investigation illustrates how children secured from doctors, hospitals, and individuals are used in dishonest schemes. A woman lived with a man who was not her husband. The man was killed in a railroad accident. The woman came to Chicago and secured a child from \_\_\_\_\_ hospital for the purpose of proving that the child was the heir. At the time the child was discovered this woman was living with another man to whom she was not married. The baby, in a neglected condition, was removed from this woman's home to a hospital. The mother of the child was afterward found. She said that she had paid the hospital for disposing of the child. As the mother herself was unable to care for the child it was turned over to the Catholic Home Finding Association. This society placed it in a good home for adoption, after the family had been thoroughly investigated.<sup>1</sup>

More frequent, more subtle to detect, but scarcely less dangerous to the child are the many instances in which the motive of the adoptive parents deviates less obviously from ethical standards, as in the following.

CASE 1—A, a boy, was adopted from an orphanage when he was between 13 and 14 months old. The adoptive father had long wanted a son. The couple had a daughter of the same age as the adoptive child, and the adoptive mother believed she was not capable of bearing any more children. The adoptive mother thought that if they would take a boy in to board perhaps her husband would be "different," less quarrelsome and sarcastic, and would be easier to get along with. Her husband suggested that they adopt a child outright. The adoptive mother visited an orphanage armed with a letter from a state's deputy. She was given the child without investigation, information about the child, or follow up. The disharmony between the parents increased. The adoptive father became a habitual drunkard, was divorced by his wife, and was finally taken to a psychopathic hospital where a classification of chronic alcoholism with deterioration was made, and he was adjudged insane. The adoptive mother remarried. A was referred to the institute at the age of 13. The problems presented at this time were unmanageability at home, resentment of his step-adoptive-father's discipline, stealing and an episode of serving as a screen for a professional thief. He was very restless and had no friends.

The following case also exemplifies the adoption of a child for ulterior motives, and incidentally the placement of a child unsuitable for adoption.

CASE 2—B, a girl aged 22 months, was adopted from an orphanage. The adoption was carried out on the insistence of the father's employer who thought it was just the thing for the family. The adoptive father urged it on his wife, thinking it would give him a permanent position. B was the youngest of five children. Her father who came from a demoralized rural family of low mentality, liberally besprinkled with alcoholism, feeble-mindedness and illegitimacy, deserted his wife and children. The mother was refused aid by the charities

because of alleged immorality, and was referred to the juvenile court. One of the children, a girl, was found to have gonorrhea and was treated, cured, and committed to a child-placing agency. The remainder of the children were committed to the care of the orphanage from which B was obtained. B was referred to the institute by the adoptive mother at the age of 6 because of failure of school progress. The adoptive mother was high strung and nervous, and wished to be rid of the child. A child protective agency had received complaint that she abused her. The psychometric examination of B revealed a mental age of 3 years and 10 months on the Stanford-Binet, giving an intelligence quotient of 58, classification, feeble-minded. The child was affected with a mild degree of stuttering and infantile mispronunciation. The adoptive parents sought to return the child to the orphanage and succeeded in returning her to her natural mother. The latter desired to resume legal custody by adoption. This is possible in Illinois only by the joint petition of the husband and wife. The whereabouts of her husband are unknown. She sought to avoid this requirement through a divorce but has not had the funds necessary for court costs. The adoptive parents who have no interest in the child, remain her legal guardians with full parental authority, although she is under the actual care of her natural mother.

Perhaps the crucial criterion is the ability of the parents to see in the child something more than a satisfaction of their own needs; the ability to recognize in the child a separate personality, with needs of its own. While some desire to relive through the child is perhaps usually present in, and normal to, parent-child relationships, prospective adoptive parents who give the clear and immediate evidence of a predominant desire to work out their own thwarted ambitions through a child should be considered unfit. On the other hand, a degree of parental pride in the achievements and accomplishments of a child is natural and desirable. It is therefore advisable, so far as possible, to place children with parents who will value the degree of achievement of which the children are capable.

The recognition of motives is often not easy. Prospective adoptive parents may not recognize their own motives in seeking a child, or, recognizing them, they may seek to conceal them. To estimate motives requires an adequate acquaintance with the prospective parents to sense the goals, values and frustrations that determine their attitudes and color their lives. The family physician is in an advantageous position for such an estimate. Of particular importance is the type of family organization in which each of the prospective parents grew up and the attitude he held toward his own parents.

The people who seek children for adoption cannot be assumed to be an average sampling of parents in the community. They differ as a group in being older and in being childless in most instances. In this connection, the role of venereal diseases in the production of sterility should not be forgotten.

A couple who have waited for years in the hope of having a child of their own and who are seeking a child for adoption are likely to be overprotective and oversolicitous toward a child that is placed in their home. Such a situation is not conducive to the development of good character. The position of such a child is an exaggeration of the usual position of an only child. Whereas the placement of a child in such a home may be of value to the parents, it will commonly be damaging to the child, as in the following instance.

CASE 3—C, a boy, aged 21 months, was referred to the institute by a child-placing agency for a routine examination previous to placement for adoption. The child was the son of a mentally retarded, suggestible Jewish girl and a gentle father about whom little is known other than that he practiced

a skilled trade. C was in good physical health. Psychometric examination resulted in a mental rating of 20 months, classification, probably slightly below average. There was some doubt as to whether or not the child was doing his best during the examination. Placement, with a view to adoption, in a middle class family was recommended, the adoption to be postponed until after reexamination one year later. The boy was referred for reexamination at the age of 3 years 4 months, intelligence quotient, 108, classification, high average. His adoptive mother, a barren woman who had been an only child but had not received in childhood as much affection as she desired was extremely overprotective, following the child about continually, calling him "lover," and asking his advice about every decision she made. She refused to permit a physical examination because the child had been recently examined and had created a fuss. The child was, obviously, very much spoiled. The adoptive mother was antagonistic to suggestions that her actions might be overprotective. She was afraid that he would not love his adoptive parents if he learned of his adoption. She wept in speaking of this and said that nothing mattered in her life except the child. It was felt that she would resent and resist any effort to modify her attitude or her behavior toward the child.

The adoptive parents who experience a sense of virtue in fulfilling the physical needs of an orphan child, yet have no appreciation that a child needs affection may be equally dangerous.

The social investigation of a prospective adoptive home is a task for which a social case worker is fitted by training. It is desirable that the responsibility for this portion of the adoption procedure be undertaken by social agencies that are properly equipped to handle it. In almost every state, even in the rural communities, such service is available, through either a state or a private agency.

The physician who has a broad understanding of people and their attitudes may nevertheless be invaluable in the estimation of the suitability of an adoptive home. Physicians are often called on by child-placing agencies to provide information about homes with which they are familiar. In this role the physician should give heed to the personalities and any apparent personality defects of the prospective parents with consideration of their probable effect on a child. Of great importance is the adjustment of the parents to each other. In the home in which there is a conflict between the parents, the child is often used as a pawn in the contest and suffers accordingly. Without a reasonable agreement between the parents on methods of training, the proper training of a child is usually impossible. It is important that the parents have, or be capable of developing, an understanding of children and of what may be reasonably expected of a child. It should be remembered that an assumed attitude will not hold up under stress. Homes in which both parents do not desire the adoption are usually unsatisfactory.

It is necessary that the adoptive parents have not only the will but also the power to give the child a fit home. This involves, in the first place, a state of reasonable health and a reasonable expectancy of a healthy life until the period when the child may be expected to become independent. Obviously a child should not be placed in a home in which either parent is suffering from open tuberculosis or is in an infectious condition with a venereal disease. It is not the custom of most child-placing agencies to require real evidence of the physical fitness of the prospective parents. Considerations of humanity would suggest that the community should demand, before the placement of a child in an adoptive home, at least that degree of investigation of the physical fitness of the parents that a life insurance

company would demand before risking its money. Mental deficiency, drug addiction, epilepsy, alcoholism, or any chronic and incapacitating disease should be considered as disqualifying an adoptive parent. It would seem that the adoption of children should be denied prospective parents who have at any time been insane.

It is, of course, further a prerequisite that the prospective adoptive parents be capable of providing the child with the necessities of life, and with educational and other advantages more or less commensurate with the standards of the community in which they live. Certain child-placing agencies require that adoptive parents have or take out an insurance policy for the protection of the child.

If a child is desired for a childless home, serious consideration should be given to the question of whether or not the adoptive parents are apt to have a child of their own. Such an event (filling the need for which the child was adopted) commonly places the adoptive child in a disadvantageous position. In the event that the adopted child displays jealousy of the natural child, or in the event that rivalry develops between them or that the level of behavior or accomplishment of the adopted child is less favorable than that of the natural child, the most broad-minded parents may find it difficult to avoid partiality toward the latter. When the adoption of a child is contemplated by a couple who already have children of comparable age, it is essential that the prospective adoptive child compare not unfavorably with the natural children.

Unmarried, divorced or widowed persons sometimes seek children for adoption. Each case should be considered on its own merits, but with the realization that in general the family set-up is the most successful.

In cases in which the suitability of parents is doubtful or perplexing, there is an advantage in consultation with a psychiatrist experienced in parent-child relationships.

#### INVESTIGATION OF THE CHILD

Although the interest of the adoptive parent should not be paramount in determining placement, it is apparent that there are obligations to an adoptive parent that should be considered in making a placement. The placement of a mentally defective child for adoption obviously is a grave injustice. It should be recognized that if prospective adoptive parents are not an average sampling of parents in the community, prospective adoptive children probably are even less so. This statement should not be taken to imply that there are not many possible adoptive homes of superior quality nor many children of superior endowment who need placement for adoption. It does imply the need for the exercise of care and caution in placement for adoption, both from the point of view of the child and from the point of view of the parents. Whereas illegitimate children are born to adults in every level and walk of life, feeble-minded girls and women in the community are notoriously apt to produce them. The factors that are responsible for the dependency of children are frequently associated with poorer rather than with better heredity, e. g., commitment of a parent to an institution for epileptics.

CASE 4—D, a boy aged 4 years was adopted by his maternal aunt and his uncle by marriage. The elopement and marriage of his parents which occurred after a few hours courtship was the result of a bet by the father a shell-shocked ne'er do well who rarely worked that he could make the mother, a pretty waitress. The parents separated after the

mother was infected with a venereal disease. At the age of 1½ years D had cerebrospinal meningitis, and he lost the power of speech, which he was beginning to develop. For two to two and one-half years after this illness he was unable to walk and his hearing was impaired. He was referred to the institute at the age of 6 by his adoptive father after he was refused admission to two schools. The neurologic examination was negative except for hyperactive tendon reflexes. The psychometric examination revealed a mental age of 2 years and 8 months, which, with a chronological age of 6 years and 10 months gave an intelligence quotient of 39, classification, feeble-minded imbecile group. The feeble-mindedness was ascribed to his attack of meningitis at 1½ years. He was restless and destructive, suggestible and easily led, given to temper tantrums and screaming. He took delight in torturing animals, practiced coprophagia and smearing, and loved to roll in the mud. He did not talk beyond a few monosyllables. At this time the adoptive parents had a baby girl, aged 5 months, of their own. D was very friendly and kind to the baby when others were present, but as soon as their backs were turned he would screw up his hands like claws and reach for the baby's neck. Once the baby was almost choked to death before some one happened in on them. The baby was in terror of D and often got into such a nervous state that the normal functioning of the alimentary tract was interfered with. D's adoptive mother was evidently attached to him and was loath to part with him. He was, in appearance, a very attractive child. The adoptive mother was in poor health and was under considerable strain in the protection of the baby from D. Commitment of D to a state institution for the feeble-minded was recommended.

Certain states make legal provision for the annulment of adoption within a specified period, i. e., five years after its completion in event the child proves to be mentally defective or epileptic. In states in which legal provision is made for the annulment of adoption, greater liberality might well be extended in permitting its completion.

No placement for adoption should be permitted until a reasonable effort has been made to ascertain whether the child is suitable for adoption. Such an effort should include the exploration of the family history for hereditary diseases, such as amaurotic family idiocy and Friedreich's ataxia, and for mental deficiency, epilepsy, alcoholism and insanity. An effort should be made to estimate the quality and social competence of the immediate relatives. The developmental history of every child placed for adoption should be scrutinized and, of course, the child should be subjected to a medical examination. Special attention should be paid to the possibility of sensory defects. Serologic tests for syphilis should not be neglected.

The behavior of the child should be noted, with an eye to estimating his aggressiveness or timidity, sociability or seclusiveness, adaptability, emotional stability, response to various measures of control and other characteristics that may be of importance in determining his adjustment in a home. Organizations undertaking placement of children for adoption should furthermore have available the services of an adequately trained clinical psychologist, to insure that feeble-minded children shall not be adopted. Caution should be used, however, in giving an unfavorable prognosis with young children of low intelligence quotients who have been in institutions or in homes that have given them little opportunity for development. The intelligence quotient of such children may show an improvement after a period of placement in a good home.

Aside from children who are mentally deficient or epileptic, blind or deaf, there are few who can be considered necessarily and permanently unsuitable for

adoption There are a number who have physical defects, which, if possible, should be remedied before placement for adoption, or, if this is impossible, of which adoptive parents should be apprised

#### INDIVIDUALIZATION OF PLACEMENT

Children are individuals and must be treated as such. A child may make a failure of adjustment in one home and a success in another, yet the first home may be entirely satisfactory for the placement of another child. In considering placement for adoption, an effort should be made to consider how the needs and abilities of the particular child would be met in the home under consideration and how the prospective parents probably would receive and manage the particular faults of the child. An advance judgment, in this regard, though it may often be misleading, will reduce the number of malplacements. A child is best placed with understanding, tolerant but not effusive parents, in a family of an intellectual and cultural level suited to his probable abilities. Consideration is due the nervous stability and usual level of tension of a child. A highly strung child is usually better placed with not too high-strung parents. Consideration of the individual child's need for affection deserves attention.

With older children, the relation between the standards of behavior which they have developed and those of the prospective adoptive home deserve consideration. Recognition is taken in the Illinois law of the need for an individual adjustment of parent and child by the provision that no adoption placement is legal on a child 14 years of age or older without his consent.

An intelligent child should have the advantages and stimulus of placement with parents who have intellectual interests. On the other hand, the placement of a dull child in a home where a superior level of academic and intellectual achievement is expected is commonly a misfortune. The need for care in this matter and the imperfect reliability of intelligence ratings of young children are revealed in the following case:

CASE 5—E, a girl, aged 3 years, was referred to the institute by a child-placing agency for examination prior to adoption. Her mother was probably feeble-minded and her father was unknown. (The husband of the mother was paralyzed and could not have been the father.) The child had been living in very unfavorable surroundings until 2½ years of age, at which time she was placed with prospective adoptive parents. During the psychometric examination the child was frightened and uncooperative. The examiner estimated that her mental age was not equal to 2 years. A provisional diagnosis of feeble-mindedness was made. It was felt, however, that her retardation might be due to her bad home background and that she might show improvement in a better environment. Reexamination was advised in one year. She was reexamined eight months later. At this time by mental tests, she graded 3 years, intelligence quotient, 88, classification dull and backward. Speech was now fairly well developed. She was reexamined at the age of 4 years and 3 months. At this time her Stanford-Binet was 3 years 8 months, intelligence quotient, 86, classification, dull and backward. It was stated at this time that there appeared to be no contraindication to adoption.

She was referred for examination by her adoptive mother at the age of 16, because of school retardation, untruthfulness and aggressive overinterest in boys. The adoptive parents who had desired to send her to college, were much distressed because of her school retardation and her lack of studiousness and school interest. Psychometric examination revealed a mental age of 10 years and 2 months which gave her an intelligence quotient of 68, classification, feeble-minded. A physical examination revealed a patent hymen and a moderate amount of purulent discharge. Smears were negative for gonococci. It was felt that a factor in the girl's delinquent

behavior was disparity between the ambitions of her adoptive parents and her own ability. She did not measure up even to the minimum requirements of her adoptive mother and lived in an atmosphere of constant criticism. Most of her untruthfulness was an attempt to put on "front." Shortly after this examination the patient was picked up by the police. She had truanted from home, and her adoptive mother refused to take her back. Commitment was arranged to a privately supported training school for delinquent girls.

Children of borderline defective intelligence are not apt to make a good adjustment in the midst of intellectual competition of urban life. They may adjust satisfactorily in simple, tolerant homes where there is little emphasis on school achievement. Such homes are more frequent in rural communities, and these surroundings provide a logical avenue for graduation into self support as a farm hand.

The choice of the age at which a child should be adopted rests between the horns of a dilemma. From the point of view of the nurture of the child it is desirable that placement should occur at as early a date as possible in order that the child may develop a feeling of security with, and of belonging to, his adoptive parents, and in order that his early training may not be disorganized by unnecessary changes of placement. However, it is impossible to avoid some gross malplacements in the policy of adoption in infancy. The policy that seems best calculated to serve the interests of all is that of early placement of children of known background who seem suitable for adoption in the homes which seem the most suitable to them, and the withholding of the transfer of legal responsibility until such time as it becomes reasonably evident that the placement is in fact successful. It should not be assumed, however, that it is always easy to terminate a bad placement.

In the case of children placed so young that an estimate of their intelligence is impossible, it is probably the wisest plan to place them with adoptive parents whose level of intelligence is more or less comparable with that of the natural parents, if they are known.

There are some differences of practice regarding the information concerning the child placed for adoption which is supplied the adoptive parents. It is my belief, in common with most workers who deal with adoption problems, that adoptive parents have a right to know the background of the child for the nurture of which they undertake responsibility, that the withholding of information which might throw into question the suitability of the child for adoption, e. g., idiopathic epilepsy in a parent, is tantamount to fraud. To those who hold this view it seems apparent that an agency does not escape the responsibility for withholding such information through a general policy of noninvestigation.

CASE 6—F, a boy, was adopted from an orphanage at the age of 2 years. The adoption was completed without investigation of the adoptive home or a study of the child's background. He had been born in an army camp, the third child in the family of a private. The adoptive parents were informed that the mother died of pneumonia when the patient was 1½ years old. The father had deserted. At the age of 8 the child was referred to the institute by his adoptive father because of stealing and lying, with the request for advice as to a school placement where rigorous discipline would be used to "break the inherited trait." F was found to be underweight of average intelligence with a good level of school achievement for his chronological and mental age. It was apparent that the importance of his stealing and lying was being distorted by the adoptive parents. The adoptive mother, an extremely domineer

ing, violent tempered woman in her third marriage, was inconsistent and unpredictable in her handling of the child. She was very affectionate to her dogs, kissing their mouths and preparing the best food for them. The adoptive father had strict disciplinary ideas and expected immediate obedience to dictatorial orders. The maternal grandmother was an understanding woman but unable adequately to buffer the child, who was in constant fear of his adoptive parents, trembling violently in their presence, and who would admit acts of which he was not guilty when charged with them, because he did not dare to deny them. The adoptive mother in her temper outbursts had threatened to kill F if her husband did not "get rid of him." The adoptive parents expressed bitterness regarding facts which they learned after the adoption of the child and which they felt the orphanage had concealed from them, viz that the parents of the child were first cousins and that the mother died not of a primary pneumonia but of tuberculosis. Their conclusion was that the child necessarily would be a mental and physical defective. This hopeless attitude was apparently a factor in their total loss of interest in the child. The child frankly hated and feared his adoptive parents, his first wish was to get away from home, his second, to have enough to eat. The mother openly admitted her dislike for the boy, although she claimed that when she originally took him she was very fond of him. She admitted that she kept him locked up and would not permit him to go to school or play with other children because she was afraid he would steal. The father unhesitatingly admitted his loss of interest in the boy.

If an adoption is decided on, it is desirable, before placement for adoption, that legal responsibility for the child be transferred from the natural parents to a responsible social agency, in order that a satisfactory placement may not be disrupted by the interference of vacillating parents.

#### THE PROBATIONARY PERIOD

The placement of a child for adoption necessitates a period of adaptation by the child and the adoptive parents. No adoption should be permitted until after a probationary period, which, under ordinary circumstances, should be a year or more, during which there has been evidence of a satisfactory parent-child relationship having been established.

Unfortunately, some child-placing organizations, certain of which have excellent physical equipment and excellent standing in the eyes of the lay and medical public, permit the completion of adoption in infancy when the suitability of the child for adoption cannot be adequately ascertained, the adoption being consummated without a real investigation of the home and without a trial period. Only the failure to make a follow-up study which is characteristic of such organizations conceals the number of malplacements which inevitably result from "over-the-counter" adoption practices.

During the probationary period contact should be maintained with the home, and the success of the placement observed. If, at the end of a fair trial, it is evident that the child is not making a reasonably satisfactory adjustment, or if the effect of the adoptive parents on the life of the child is not a reasonably wholesome one, the placement should be terminated. If the success of the placement is doubtful, the probationary period should be extended. If the placement is judged to be successful and a re-examination of the child reveals it to be suitable for adoption, the adoption should be permitted. In view of the desirability of the child being rooted in the adoptive home as early as possible, and the advantage of the early completion of the adoption in favorable cases, it is recommended that the practice of permitting early adoption be as liberal as is consistent with reasonable caution.

The following practice, based on a consideration of the relative unreliability of intelligence ratings of young children, is recommended as reasonably cautious in regard to the evidence of intellectual adequacy required before the consummation of adoption.

Each child should be tested before and at the completion of the probationary period of one year. It is desirable, particularly with children under 4 years, that each examination should include two tests. The tests should be administered by an adequately trained clinical psychologist.

In cases in which the results of the tests are discrepant with the rough estimation of the child's intelligence from the observation of his behavior, judgment should be withheld until the discrepancy is dissolved.

1 With children, aged 1 year or older, indication of very superior intelligence is adequate for adoption.

2 With children, aged 18 months or older, indication of superior intelligence (intelligence quotient 110 or above) is adequate for adoption.

3 With children, aged 2 years or older, indication of intelligence at or above the presumed mean (intelligence quotient 100 or above) is adequate for adoption.

4 With children, aged 3 years or older, indication of intelligence falling in the grouping "average" or above (intelligence quotient 90 or above) is adequate for adoption.

5 With children, aged 4 years or older, indication of intelligence falling at or above the middle of the grouping "dull and backward" (intelligence quotient 85 or above) is adequate for adoption.

6 With children, aged 5 years or older, indication of intelligence above "borderline defective" (intelligence quotient 80 or above) is adequate for adoption.

Adoptions of children with an intelligence quotient between 70 and 80 are advisable only under circumstances particularly favorable to the adjustment of such children.

In certain cases the foster parents form an attachment for a child placed with them whose development does not justify the recommendation for adoption. In these cases the parents should be frankly advised of the experts' opinions, but it may be considered proper to permit the adoption of the child against advice.

Many adoptive parents seek to conceal from their adoptive children the fact of adoption. The motive for the concealment is apparently the fear that they will not be accepted as parents by the child if it learns of its adoption. If concealment were likely to be successful, the element of deception might be overlooked. Experience indicates, however, that even when the adoptive parents move to another neighborhood or to another city the adopted child, with few, if any, exceptions, ultimately learns of his adoption. The knowledge, usually coming relatively late, from an indirect and sometimes unsympathetic source, often produces an emotional crisis in the child's life, frequently with damaging results. The estrangement of child and parents may take its origin from this crisis, sometimes without recognition by the parents of the cause. The child who has been told of his adoption when young, at the age of 4 or 5, is forearmed against this type of damage. The knowledge need not interfere with the child's sense of security in his parents, indeed, clever parents sometimes capitalize the fact to add to the child's security by pointing out that he was selected because they wanted him especially. It is highly important, in order to avoid future perplexing doubts, that an adopted child be told of his identity and given any possible favorable information about his parents.

Infants and children judged to be unsuitable for adoption may be cared for by boarding-home place-

ment, under the supervision of a suitable child-placing agency, or by institutional placement, as may seem best, depending on the child and the resources available

## SUMMARY

It is the duty of physicians to familiarize themselves with the factors determining good adoption practice and, wherever possible, to cooperate with careful child-placing agencies

Before placement of a child in adoption is decided on, a canvass should be made of all possible resources for aiding the parents to maintain the child. Adoption should be resorted to only if a satisfactory arrangement of maintaining the child with one or both parents is impossible

Placement for adoption should not be permitted unless the home, after careful investigation, appears to be suitable. An effort should be made to ascertain the motive prompting the prospective parents to adopt a child. The state of health of the prospective parents should be determined, with especial attention to the detection of tuberculosis and venereal diseases. The personalities and personality defects of the prospective parents should be noted, and their ability to provide a child with the security and advantages usual to the community determined

No placement for adoption should be permitted unless the child after a careful study appears suitable. Such study should include exploration of the family history when this is possible, review of the developmental history of the child, physical examination, psychologic examination and observation of the child's behavior

Placement for adoption should be individualized. It is desirable that a child be placed in a home capable of meeting his needs, and of a level of standards suitable to his abilities

Legal responsibility for the child should be transferred to a suitable social agency before placement for adoption

No legal adoption should be permitted until a probationary period reveals that a reasonably satisfactory parent-child adjustment has been established and that the child is adjusting in the home, and until reexamination of the child establishes that he is suitable for adoption. The probationary period should ordinarily not be less than a year. In doubtful cases it should be extended

Children not suitable for adoption may be cared for in boarding homes, under the supervision of suitable child-placing agencies, or in institutions

907 South Lincoln Street

**Symptoms of Rupture of Intracranial Aneurysm**—The characteristic symptomatology of aneurysms begins when rupture occurs. Premonitory symptoms of an indefinite character may precede rupture for several days. The rupture of the aneurysm is usually manifested by a sudden apoplectic seizure with loss of consciousness, vomiting and sometimes a convulsion. Death may occur at this time. If fatal hemorrhage does not occur, the patient gradually regains consciousness and complains of severe fronto-occipital headache, stiffness of the neck and perhaps pains in the extremities due to irritation of the meninges by the extravasation of blood into the subarachnoid space. The clinical picture resembles a fulminating septic meningitis. Frequently the focal signs, notably palsy of the third nerve appear at this time. The preexisting focal signs are increased owing to the formation of a clot around the aneurysm—Garvey P H. Aneurysms of the Circle of Willis, *Arch Ophth* 11 1132 (June) 1934

## Clinical Notes, Suggestions and New Instruments

### CULTIVATION OF THE VIRUS OF LYMPHOGRANULOMA INGUINALE AND ITS USE IN THERAPEUTIC INOCULATION

PRELIMINARY REPORT

JOSEPH T. TAMURA, M.Sc., CINCINNATI

Heretofore, as far as I can learn<sup>1</sup> attempts to cultivate the etiologic agent of lymphogranuloma inguinale have been failures. I have been successful by utilizing the medium devised by Matland, Laing and Lyth<sup>2</sup> for the cultivation of vaccinia virus. This medium is made by placing sterile bits of rabbit tissue in Tyrode's solution. I have used guinea pig tissue instead of rabbit

## METHOD OF CULTIVATION

When pus is removed aseptically from a bubo that has not been exposed to external contamination and is found to be bacteriologically sterile, it is diluted 1:5 with sterile saline solution. Now, when from 0.02 to 0.03 cc of the diluted pus is planted in the Tyrode's solution containing a piece of guinea pig kidney or liver and incubated at 37.5°C, a peculiar cloudiness appears throughout the supernatant fluid in from thirty-six to forty-eight hours. Control tubes of the medium incubated at the same time remain perfectly clear. This cloudiness can be transmitted from tube to tube and in one instance was carried through twenty-four subcultures, when the procedure was discontinued

In my experience, as in that of others, cultures made from bubonic pus when planted on a wide variety of bacteriologic mediums and grown aerobically, under partial tension of oxygen or anaerobically, remain free of visible growth. When the cloudy supernatant fluid in the tissue-Tyrode medium is examined or cultured, nothing resembling ordinary bacteria is to be found. The appearance of the cloudiness is followed by a slow disintegration of the tissue. Such disintegration does not occur in control tubes

When transfer is made from twelve day old cultures it is successful. In a fourteen day old culture the cloudiness seems to settle out and when the clear supernatant fluid is subcultured it no longer produces cloudiness

Attempts to see the etiologic agent in cloudy fluid have failed, with the exception that peculiar granules are brought out by Gram's stain and these are absent in controls

While I think I have enough proof that the cloudy culture supernatant fluid contains the etiologic agent, it is interesting to note that pus from three cases failed to produce cloudiness in the medium. However, Frei antigens prepared from the pus in these cases also failed to give positive skin reactions in other proved cases

Subcultures from a 1:10,000 dilution of the pus did not yield growth, but from a 1:1,000 dilution did

## FILTRABILITY

When diluted pus or the cloudy supernatant fluid in culture is passed through the Berkefeld N filter, the filtrate will produce cloudiness on subculture

## PATHOCENICITY

When 1 cc of the cloudy supernatant fluid is inoculated subcutaneously into the groin of a guinea-pig a lymphadenitis is produced in from two to three days. The glands gradually increase in diameter and in ten or twelve days may measure 15 mm and the overlying skin becomes adherent to the affected glands, after which they tend to disappear spontaneously. This is comparable to that which one can accomplish by direct inoculation with human pus. Such culture subinoculations have succeeded when the fourth, sixth and eighth subcultures were

The Department of Dermatology cooperated in this work. From the Department of Bacteriology and Hygiene, University of Cincinnati College of Medicine

used The etiologic agent has been passed from culture to guinea pig, then from guinea-pig to the medium, from this culture to a subculture, and then back to the guinea-pig, as often as four times (to date)

#### USE OF CULTURE ANTIGEN FOR DIAGNOSIS

The cloudy supernatant fluid from subcultures was heated to 60 C for two hours on one day and at the same temperature for one hour on the following day as in the well known method of preparing Frei's antigen from pus When such heated culture antigen preserved with 1 10,000 merthiolate is injected intradermally into patients, it gives just as marked reactions as does the Frei antigen When the twenty-third subculture in one series was heated for antigen it was found to be just as active as antigen prepared from earlier subcultures As in the case with the Frei antigen, the culture antigen gives no reaction in normal individuals

#### USE OF CULTURE ANTIGEN FOR TREATMENT

I have nine cases, showing active inguinal manifestation of the disease, under treatment using heated culture antigen as a vaccine administered subcutaneously Of these, three cases showed such marked improvement that they were considered cured in eight weeks Accompanying the clinical improvement there was a marked reduction in skin sensitivity Other cases appear to be following a similar course

Beneficial therapeutic effects, following the intradermal inoculation of Frei's antigen, has been reported recently by Wien and Perlstein,<sup>3</sup> who refer to the previous work of Hermans and Gay-Prieto

#### SUMMARY

When pus from lymphogranuloma inguinale is planted in the tissue-Tyrod medium used by Matland and his co workers for the cultivation of vaccinia virus it becomes cloudy The etiologic agent produces this cloudiness which is transmittable in serial cultures, or serial cultures alternating with guinea-pig inoculations The etiologic agent in pus or cloudy supernatant culture fluid passes the Berkefeld N filter The heated cultures have been used successfully in making diagnosis by the intradermal skin test and for cure by subcutaneous inoculation therapy

#### BITE BY A SNAKE IN A BUNCH OF BANANAS

MARCOS FERNANDEZ, MD MILWAUKEE

The importance of modern rapid transportation methods, such as the airplane, in the transmission of tropical diseases to nontropical lands has been dramatically demonstrated in recent years by the appearance of several exotic diseases in the northern part of the United States

The following report, demonstrating a similar paradox, illustrates the possibility of being bitten by a tropical snake in the center of a great northern city

#### REPORT OF CASE

J M a truck driver was unloading bunches of bananas in Milwaukee, March 5 1934 when he felt something sting him on the hand His search revealed a snake, 37 inches (94 cm) in length, in the bunch of bananas

I examined the victim thirty four minutes after the bite and found two small bleeding punctures 1 cm apart on the palmar surface of the middle phalanx of the third finger of the right hand The finger showed a mottled swelling extending up the hand to the metacarpal region The pulse rate was 102 and the respiration rate 28 The patient complained of pain in the affected area with beginning nausea

A tourniquet was placed just above the elbow (a single-bone extremity) and was tightened enough to cut off the venous return A fairly deep incision connecting the two puncture wounds allowed free bleeding which the victim aided by applying vigorous suction by mouth

<sup>1</sup> Wien M S and Perlstein Minnie O Intradermal Treatment of Lymphogranuloma Inguinale Arch Dermat Syph 1933 28 42 (July) 1933

From the Marquette University School of Medicine

An anti-snake-bite serum (Antivenin [Necrotic Crotalidae]-Mulford) was quickly obtained from a nearby wholesale drug house, a dose of 10 cc was given intravenously and the same amount was administered intramuscularly One-half hour later 10 cc of antivenin was given subcutaneously Whereas this anti-snake-bite serum was prepared against North American vipers, the fact that the tropical snake that had bitten the patient was a member of the viper family led me to reason that the serum would be effective to some extent at least

For two hours thereafter at intervals of fifteen minutes the tourniquet was released for periods of three minutes each and reapplied 2 inches higher up the extremity each time This was done to prevent gangrene and to permit the venom to enter the general circulation in such small amounts that it could be readily oxidized

The pain and swelling gradually disappeared and the patient was practically relieved from the symptoms at the end of six hours He returned to his work the following day

#### COMMENT

It was ascertained that the bananas had been brought from Colombia, where it is the custom to cut the bunches from the trees and lay them on the ground to be picked up later Often the bunches remain on the ground for several hours during the night Evidently the snake had entered the bunch in search of mice or other vermin and had secreted itself in the bunch when it was removed to the banana boat

To my knowledge poisonous snakes have been found in bunches of bananas on five occasions in Milwaukee alone Three of the snakes were examined and were found to be pit vipers (two Mapanas and one Lancetilla), i e, having a blind pouch between the eye and the nostril However, the reported case is the only instance in which a human being was bitten, and it is recorded because it is probable that there will be similar occurrences in the future

It is a common experience to find nonpoisonous snakes in bunches of bananas They are usually members of the boa family (boa imperator, or small boa constrictors) which climb the banana trees in search of spiders and small animals and are caught there when the bunch is cut off They do not have the blind pouch between the eye and the nostril which characterizes the pit vipers, and they are gray with spots on the back Since their fangs are not perforated and are located in the back of the mouth they have no efficient mechanism for injecting venom and are not dangerous However, they are vicious at times and can inflict a painful bite

561 North Fifteenth Street

#### FIBROMA OF VAGINA RESSEMBLING CYSTOCELE

HAMLIN MATTSON, MD MINNEAPOLIS

Soft fibromas are found especially in the skin and mucous membranes About 200 cases of fibromyoma of the vagina have been reported<sup>1</sup> Such tumors may occur at any age though usually they are found between the ages of 20 and 50 years<sup>2</sup> They are situated usually in the midline, and four out of five are in the anterior wall, it has been estimated<sup>3</sup> Such tumors exhibit central expansive growth rarely attain more than moderate size and rarely become malignant The blood vessels supplying such tumors grow out from the capillaries of the surrounding normal tissue<sup>4</sup> Hence the tumor tissue is prone to degeneration softening and ulceration Because of such characteristics it is possible that tumors of this type are assumed to be cystoceles and rectoceles and are overlooked more often than has hitherto been suspected Werner<sup>5</sup> and more recently Downing<sup>6</sup> have pointed out the similarity of the presenting evidence

<sup>4</sup> Bell E T Textbook of Pathology ed 1, Philadelphia Lea & Febiger 1930 p 173

<sup>5</sup> Downing Wendell Anterior Colpocele Due to Fibromyoma J A M A 28 1157 1158 (April 2) 1932

An instance of soft fibroma of the vagina that resembled cystocele in a nulliparous woman, F J, is here presented

F J, a woman, aged 31, single, a nullipara, seen Jan 18, 1931, complained that intermittently for twelve years she had been bothered by a feeling of weight in the vagina. Such a sensation would be felt for three or four hours at intervals of from four to six weeks, especially when fatigued, after severe exertion or at menstruation. After three or four hours she would feel normal again. Micturition was not disturbed. She had no other complaints. The difficulty had been thought to be due to cystocele. There was nothing significant in the

Section of soft fibroma of the vagina showing small branched connective tissue cells with some connective tissue fibers in an abundant homogeneous matrix. Slightly reduced from a photomicrograph with a magnification of 125 diameters. Hematoxylin and eosin stain.

family or menstrual history. She had neuromuscular pains at the age of 16. A tonsillectomy was performed in 1918 though she has experienced more frequent sore throats since that procedure. The appendix was removed in 1920. In March 1929 she sustained a fall, following which she was unconscious. Since the onset of menstruation she had noticed a moderate leukorrhea, though not enough to wear a pad.

The anterior wall of the vagina protruded at the introitus and when the labia were separated the appearance was typical of a cystocele graded 2 on the basis of 4. The aspects on palpation were similar to those of cystocele with the urinary bladder empty. When the bladder was distended a soft mass could be felt at the site of the protrusion, and on cystoscopic examination a hillock presented instead of the depression of a cystocele. The cervix was definitely cystic, otherwise the pelvic examination was negative. Macromastia, graded 2 on a basis of 4, was present. Urinalysis showed 4 pus cells in the high dry field after centrifugation for three minutes. Otherwise the urine was normal on routine examination. There were 4,500,000 red blood cells and 12,000 white blood cells in each cubic millimeter of blood. The concentration of hemoglobin was 128 Gm (normal 16) for each hundred cubic centimeters of blood. The blood pressure, pulse and temperature were normal.

A urethral catheter was inserted as a guide, and January 18, a rounded tumor was nucleated by blunt dissection through an elliptic incision in the anterior vaginal wall. The procedure was carried out under spinal anesthesia and was uneventful. The function of the bladder was not disturbed. A retention catheter was kept in for five days.

The tumor measured 5 by 3.5 cm and weighed 20 Gm. It was soft and gray, and grossly it had the uniform consistency throughout of whartonian jelly. Dr. E. T. Bell, of the department of pathology of the University of Minnesota, diagnosed soft fibroma. The tumor showed the same microscopic structure in all sections.

Convalescence was uneventful. Feb. 14, 1934, the patient reported that she had felt well since the removal of the tumor.

CREATINURIA IN ADOLESCENT MALES II THE EFFECTS OF THE ORAL ADMINISTRATION OF EPHEDRINE SULPHATE

ARTHUR B. LIGHT, M.D. AND CLARY R. WARREN, A.B.  
LAWRENCEVILLE, N. J.

Edgeworth<sup>1</sup> reported the first case of myasthenia gravis in which ephedrine sulphate was used with beneficial results. Since this publication, ephedrine sulphate has at times been employed in conjunction with glycine in the treatment of this disease. Studies of its effects, when used alone, on the creatine excretion in cases of myasthenia gravis have to our knowledge not been made. Reinhold and his associates<sup>2</sup> report a probable case of progressive muscular dystrophy in which ephedrine was used in conjunction with glycine with a resulting definite increase in the twenty-four hour creatine excretion. In this paper are reported the results obtained when ephedrine was administered orally to healthy adolescent males known to excrete creatine. These boys were all students engaged in a similar daily routine of study, exercise and diet during the period of investigation.

METHOD OF INVESTIGATION

The preformed and total creatinine determinations were made according to the methods recorded in our first paper.<sup>3</sup> These analyses were again checked by duplicate determinations of controls to which known quantities of pure creatine in solution had been added. The twenty-four hour urinary collections were carried out as originally reported.

EXPERIMENTAL PROCEDURE

The subjects in these experiments made twenty-four hour collections of urine for three successive days, the first and third days serving as controls. On the second day each subject received ephedrine sulphate. In order to offset any effects of exercise, the first capsule containing 25 mg. was given half an hour before rising (6:30 a.m.). Additional capsules were given at 10:30 a.m. and 2:30, 4:30 and 8:30 p.m., making a total of 100 mg. during the twenty-four hour period. The capsule at 8:30 p.m. was omitted in the last three subjects.

It was noted that without exception the administration of ephedrine sulphate was accompanied by a complete disappearance

(controls indicate an error of  $\pm 10$  mg. of creatine per liter of urine) of creatine from the twenty-four hour specimens when the amounts excreted during the control periods varied from 19 to 136 mg. Two additional subjects not listed in the accompanying table showed the same results, although they failed to make complete urinary collections on one of the control days. On the other hand no changes in either the average preformed creatinine or the urinary outputs were detected.

3 Light, A. B., and Warren, C. R. J. Biol. Chem. 104: 121 (Jan.) 1934.

COMMENT

No explanation is at hand to account for this action of ephedrine. The blood pressure and pulse rate of those of our subjects in which these determinations were made were definitely increased. Practically all of them complained of slight headache, a few experienced nervousness and slight weakness, and one subject noted definite nausea. Despite these symptoms, the amount of food taken, particularly the protein intake, remained the same for each day. Three subjects ate all their meals in the infirmary under the direct supervision of the nursing staff. The amount of exercise remained the same on each of the three days.

CONCLUSIONS

The oral administration of 25 mg of ephedrine sulphate three or four times daily causes a temporary cessation of creatinuria among adolescent males. On the other hand it exerts practically no influence on the twenty-four hour preformed creatinine and urinary outputs.

## Therapeutics

### THE THERAPY OF THE COOK COUNTY HOSPITAL

EDITED BY BERNARD FANTUS, MD  
CHICAGO

*NOTE.—In their elaboration these articles are submitted to the members of the attending staff of the Cook County Hospital by the director of therapeutics Dr. Bernard Fantus. The views expressed by various members are incorporated in the final draft prepared for publication. The series of articles will be continued from time to time in these columns.—Ed*

#### THERAPY OF FURUNCULOSIS

The more severe cases require both local and general treatment. Special methods are indicated in furuncle of the external auditory meatus, of the nares and of the lips.

##### LOCAL TREATMENT

Abortive treatment, if applied early, may succeed. It consists of: 1. Avoidance of traumatism, even of the slightest degree such as pressure and friction from clothing, as well as squeezing. 2. Improving the inflammatory reaction by (a) heavy coating with full strength Tincture of Iodine, or (b) roentgen irradiation with 180 kilovolts, 300 roentgens, with a filter of 0.25 mm of copper and 1 mm of aluminum, at 50 cm distance and with 30 milliamperes, applied to a rather large field. The two (a and b) methods must not be combined.

Inevitable suppuration indicates: 1. Epilation of the skin overlying the boil, and the surrounding area, by shaving. 2. Induction of hyperemia and softening by hot boric acid compresses changed every hour or two until there is indication of the place of pointing. A simple alternative treatment, when the hot compress is not available, is application by means of adhesive plaster of a thin disk of soap the size of a thumb nail. 3. Evacuation of the abscess under local ethyl chloride anesthesia, by puncture of the thinned epidermis or excision of the top. Free incision is not desirable. Squeezing is taboo. 4. Absorbent dressings changed often enough to maintain drainage, i. e. to prevent crust formation in the upper layers of the dressing. 5. Protection of the surrounding skin by washing with ether and alcohol and the application of Paste of Zinc Oxide dusted with talcum powder. 6. Stimulation of healing, after removal of the core (which must never be done forcibly) by Balsam of Peru dressing. Dressing is continued until healing is complete and there are no crusts that might cause autoinoculation.

Recurrence of the furuncles should be prevented by: 1. Washing the affected area with Tincture of Green Soap and a face brush and hot towel, followed by alcohol or other disinfectant lotion (prescription 1).

##### PREScription 1—Salicylic Acid Lotion

R	Salicylic acid	2.00 Gm
	Alcohol	75.00 cc
	Water	to make 100.00 cc
M	Label: Apply locally	

2. Frequent hot baths and changes of underclothing should be given. 3. The skin should be kept dry by dusting with Salicylated Talcum Powder (prescription 2). 4. For areas (back of the neck or the axillae) in

##### PREScription 2—Salicylic Acid Dusting Powder

R	Salicylic acid	1.50 Gm
	Talcum	30.00 Gm
M	Label: Dusting powder	

which boils obstinately recur, a series of five to six roentgen treatments (85 kilovolts, no filter, 75 roentgens, once a week) often suffices for a permanent cure (possibly, in part, by antagonizing hyperhidrosis).

##### GENERAL TREATMENT

Impairment of nutrition should be corrected. In all cases of furunculosis the patient should be examined for diabetes, nephritis or anemia and appropriate treatment instituted if any one of these conditions is found. Obesity may require attention. Vitamin deficiency, if present, might be corrected by cod liver oil, general ultraviolet irradiation or sun baths and possibly by brewers' yeast.

Resistance should be improved by (a) removal of foci of infection, which may keep general resistance low. (b) Vaccine therapy with autogenous vaccine, starting several days after disappearance of the acute lesions on account of the possibility of the negative phase aggravating the condition. The dose aimed at should be such as to cause a definite but mild local reaction. If the reaction has been excessive, the dose is repeated, otherwise it is gradually increased until the patient tolerates without reaction possibly ten times the dose that at first produced a reaction. The interval between doses should be such as to permit complete disappearance of all phenomena of reaction, possibly three, five or seven days.

##### FURUNCLES IN SPECIAL LOCATIONS

In all of these localizations of furuncles, roentgen irradiation should be employed. In the acute lesions 140 kilovolts is used, with 0.25 mm of copper and 1 mm of aluminum and 300 roentgens the first day and 150 roentgens the second day. In subacute lesions 150 roentgens is used for three or four consecutive days.

*Of External Auditory Canal*—Before the pointing of the abscess, one should relieve pain, which is usually severe and increased by opening the mouth (a point of value in differentiation from otitis media) by use of a systemic analgesic (see Therapy of Pain). Irrigations, attempts at local analgesia, and early incisions are useless. 2. Alcohol (95 per cent) should be instilled hourly, the head being kept inclined to the well side for five minutes. Heat should be applied to the auricle and the side of face by fomentation, poultice or incandescent light.

The appearance of a yellowish point of softening indicates incision with the point of a bistoury. The pus should be wiped out frequently (every hour or two) with cotton applicators dipped in saturated alcoholic solution of boric acid (3 per cent).

Recurrence may be prevented after healing by 1 Boric acid alcohol instillation (prescription 3) morning

#### PRESCRIPTION 3—Boric Acid Alcohol

R	Boric acid	0.90 Gm
	Alcohol	30.00 cc
M	Label	Ear lotion

and evening 2 Relief of itching by salicylic acid oil (1 10) with prohibition of scratching by introduction of any foreign body into auditory canal 3 Autogenous vaccine, in case of recurrence in spite of these precautions

**Nasal Furuncle**—Application inside and outside of the nostril of small flat cotton compresses saturated with hot boric acid solution favors earlier opening on the inside of the nose than would otherwise occur "Picking" of the nose should be forbidden

**Upper Lip Furuncle and Facial Furuncle**—These are deservedly dreaded because, no matter how mildly they start, they may be suddenly followed by intense swelling of the lip and carbuncle formation, as well as, because of the richness of the veins in this area, they may become complicated by thrombophlebitis, meningitis, septicemia and death. Hence the most innocent looking furuncle of the lip or face should be treated by 1 Absolute immobilization of the part speaking, eating or drinking must be forbidden, feeding being done through a tube 2 Prohibition of trauma, such as scratching or squeezing 3 Energetic local and general treatment in accordance with the principles laid down, especially by frequent irrigation of the under-surface of the lip with warm boric acid solution and roentgen irradiation, as already described

## Council on Pharmacy and Chemistry

### NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary

**HIPPURAN**—Sodium ortho iodohippurate— $C_6H_4CONHCH_2COONa + 2H_2O$ . The sodium salt of *o*-iodohippuric acid. Hippuran contains 38.8 per cent of iodine, when calculated to the dried substance.

**Actions and Uses**—Hippuran is proposed for use as a radiopaque agent for intravenous, oral or retrograde urography. When used by the intravenous route, irritation at the site of injection is stated not to occur and systemic reactions appear to be unusual, a sensation of generalized warmth is said to be the most common side-effect, nausea occurs occasionally and vomiting rarely. Fasting and dehydration of patients preliminary to administration of the drug are usually employed. Pressure over the bladder region is employed by some clinicians, this is released immediately before the first exposure and is replaced until the next. Ordinarily the first film is exposed about ten minutes after injection and two subsequent pictures are taken at fifteen or twenty minute intervals. In case excretion is delayed, later exposures may be necessary.

Results with oral administration of the drug are less satisfactory but a sufficiently high percentage of successful pictures appear to be obtained to make this method worthy of trial in occasional cases in which intravenous or retrograde urography is not feasible. The somewhat objectionable taste of the compound usually does not militate against its ingestion. Toxic effects after oral administration have not been reported. Pictures are taken 60, 90, 120 and 150 minutes after oral administration. The use of moderate compression over the bladder region is recommended in the intervals between exposures. While the iodine in hippuran is firmly bound, the compound

should nevertheless be used with caution if at all in patients with hyperthyroidism and tuberculosis. The use of the drug is contraindicated in severe liver disorders, nephritis and uremia. In suspected cases preliminary hepatic and renal function tests should be employed.

Satisfactory visualization has been reported with hippuran when employed by the retrograde method for urethrograms, cystograms or pyelograms. There is said to be little or no tissue irritation with effective concentrations.

**Dosage**—For intravenous use, 25 cc of a solution containing 12 Gm of hippuran, previously warmed to body temperature is injected into the cubital vein. Young children are given proportionately smaller doses. For oral use, 12 Gm of hippuran is dissolved in 75 cc of simple syrup. For children, 10 Gm is employed. For retrograde use, hippuran is employed in 15 to 20 per cent solution for pyelography or 3 to 5 per cent solution for cystography. The solution may be made either by diluting the ampule solution with sterile distilled water or by dissolving the crystals in distilled water, filtering and sterilizing by heat.

Manufactured by Mallinckrodt Chemical Works, St. Louis, U. S. patent and trademark applied for.

**Hippuran (Crystals) 12 Gm. vial**

**Sterile Solution Hippuran 25 cc size** 25 cc contains 12 Gm hippuran. Hippuran occurs as a white crystalline powder possessing a faint odor and an alkaline taste, very soluble in water, freely soluble in ethyl alcohol and soluble in dilute alkali. An aqueous solution is neutral or faintly alkaline to litmus.

Fuse about 0.2 Gm of hippuran with 2 Gm of powdered sodium hydroxide; it decomposes with the evolution of iodine vapors and ammonia. Dissolve about 0.5 Gm of hippuran in 100 cc of water; add an excess of diluted hydrochloric acid; collect the resultant *o*-iodohippuric acid on a filter wash and dry at 110°C; it melts at 171 to 174°C. To 1 cc of the foregoing filtrate add 10 cc of 0.5% zinc acetate solution; a yellow precipitate results. Transfer about 0.5 Gm of hippuran to a glass stoppered cylinder; add 25 cc of a diluted nitric acid (one part diluted nitric acid and 5 parts water); shake for five minutes; filter; the filtrate yields no distinct opalescence on the addition of 2 cc silver nitrate solution (absence of inorganic halides). Dissolve about 0.5 Gm of hippuran in 50 cc of water; add 5 cc of diluted hydrochloric acid; filter; separate portions of 10 cc each of the filtrate; yield no turbidity on the addition of 1 cc of barium chloride solution (sulphate); no coloration or precipitation on saturation with hydrogen sulphide (salts of heavy metals).

Dry about 1 Gm of hippuran, accurately weighed to constant weight at 100°C; the loss in weight is not more than 10 per cent nor less than 6 per cent. Boil about 1 Gm of hippuran accurately weighed with 10 cc of benzene for fifteen minutes; replacing the evaporated liquid if necessary; decant the supernatant liquid through filter paper and wash filter with 10 cc and 5 cc portions respectively; evaporate the combined filtrates to dryness in a tared beaker and dry to constant weight at 100°C; the residue does not exceed 0.2 per cent (uncombined *o*-iodohippuric acid). Transfer about 0.5 Gm of hippuran accurately weighed to a 500 cc kjeldahl flask; determine the nitrogen content according to the official method described in Official and Tentative Methods of Analysis of the Association of Official Agricultural Chemists, third edition, page 20, chapter 2, paragraph 22; the percentage of nitrogen corresponds to not less than 4.1 per cent nor more than 4.4 per cent when calculated to the dried substance. Weigh accurately about 1 Gm of hippuran in a tared platinum dish; add 5 cc of sulphuric acid; heat cautiously while fumes of iodine and sulphur trioxide are evolved; repeat twice using portions of 1 cc each of sulphuric acid; add about 0.5 Gm of ammonium carbonate; ignite to constant weight and weigh as sodium sulphate; the sodium found corresponds to not less than 6.8 per cent nor more than 7.3 per cent when calculated to the dried substance. Transfer about 0.5 Gm of hippuran to a Parr sulphur bomb; determine the iodine content by the Lemp-Broderson method (*J. Am. Chem. Soc.* 39: 2069); the amount of iodine found corresponds to not less than 38.5 per cent nor more than 39 per cent when calculated to the dried substance.

**DEXTROSE** (See New and Nonofficial Remedies, 1934, p. 270)

The following dosage forms have been accepted:

**Ampoules Glucose (Dextrose U. S. P.) Lilly, Unbuffered 25 Gm. 50 cc.** Each ampule contains dextrose U. S. P. 25 Gm in distilled water to make 50 cc.

Prepared by Eli Lilly & Co. Indianapolis

**Ampoules Glucose (Dextrose U. S. P.) Lilly, Buffered 25 Gm. 50 cc.** Each ampule contains dextrose U. S. P. 25 Gm in distilled water to make 50 cc. The solution is buffered with sodium citrate 0.25 per cent.

Prepared by Eli Lilly & Co. Indianapolis

**Ampoules Glucose (Dextrose U. S. P.) Lilly, Unbuffered 50 Gm. 100 cc.** Each ampule contains dextrose U. S. P. 50 Gm in distilled water to make 100 cc.

Prepared by Eli Lilly & Co. Indianapolis

**ERYSIPELAS STREPTOCOCCUS ANTITOXIN** (See New and Nonofficial Remedies, 1934, p. 369)

United States Standard Products Company, Woodworth, Wis.

**Erysipelas Streptococcus Antitoxin (Refined and Concentrated)**—Prepared by immunizing horses with toxin and cultures of streptococci isolated from erysipelas cases. When tests of trial bleedings indicate that the potency is sufficiently high the horses are bled and the plasma concentrated and refined by methods similar to those used for other antitoxins. The product is preserved with 0.4 per cent cresol in a 50 per cent ether solution. Potency tests are carried out by making serial dilutions of the antitoxin with equal amounts of erysipelas toxin and determining the titer by the rabbit ear method which is a toxin neutralization test.

Marketed in packages of one syringe containing approximately 15 cc the average initial therapeutic dose.

**Committee on Foods**

THE COMMITTEE HAS AUTHORIZED PUBLICATION OF THE FOLLOWING  
REPORTS  
RAYMOND HERTWIG Secretary

**NOT ACCEPTABLE**

**SIMS MALT-O-WHEAT BREAKFAST CEREAL  
WHOLE WHEAT (COARSE BRAN  
REMOVED) FLAVORED WITH  
TOASTED BARLEY,  
ULTRA-VIOLET  
RAYED**

Sims, Inc., St Paul, submitted to the Committee on Foods a packaged coarsely granular durum wheat (coarse bran and some flour removed) containing a small amount of toasted barley malt, called Sims Malt-O-Wheat Breakfast Cereal. The product is treated with ultraviolet rays and heat to destroy insects.

Analysis (submitted by manufacturer) —	per cent
Moisture	8.2
Ash	1.7
Fat (ether extraction method)	2.5
Protein (N × 6.25)	16.8
Crude fiber	2.7
Carbohydrates other than crude fiber (by difference)	68.1

**Discussion of Label**—The label carries the following statements

Malt O Wheat Breakfast Cereal ultra violet rayed  
treated by our special patented ultra violet ray process to insure absolute  
purity and cleanliness Breakfast monotony can be avoided by  
serving this healthful cereal healthful food The essen-  
tial minerals and vitamins of the whole wheat are carefully retained  
Every precaution is taken to safeguard the high stand-  
ard of healthfulness recognized by thousands of dietitians and physicians  
who use and recommend Sims The addition of caramelized malt  
creates the distinctive flavor blend No single article of food  
contains such an abundance of energy units balanced with other nec-  
essary elements—proteins minerals vitamins—as wheat

The name Malt-O-Wheat Breakfast Cereal unduly emphasizes the malt ingredient, which is present only in small quantity. The unqualified prominent claim, "ultra-violet rayed" incorrectly implies that the cereal is irradiated by this well known process for producing vitamin D. The treatment is for destroying insects only but does not insure absolute purity and cleanliness.

The cereal is not more "healthful" than other common foods. It will not correct any abnormal condition or actively improve health, nor does it possess any unique health-giving properties as implied by the designations "healthful cereal" and "healthful food." Statements such as "the essential minerals and vitamins of the whole wheat are carefully retained" should name the mineral and vitamins, to avoid inferences that wheat contains all the 'essential minerals and vitamins'.

No evidence was furnished indicating that "thousands of dietitians and physicians use and recommend Sims." Vague alleged recommendations of physicians or dietitians deceptively convey by implication imaginary special nutritional or therapeutic values to the product. Recommendations for a food should specifically state why the food is recommended or for what purpose. The added toasted malt should not be given the unrecognized name 'caramelized malt.' Wheat does not warrant being singled out from common foods as containing a special 'balance' of energy units, proteins minerals, vitamins" thereby incorrectly suggesting unusual nutritional values due to uniquely proportioned 'minerals proteins, vitamins'.

The label claims in considerable part are misinformative and misleading. Advertising should truthfully and appropriately, in terms readily understandable by the public present the values of foods.

The company was informed of the criticisms and recommendations of the Committee but has not demonstrated compliance. This cereal will therefore not be listed among the Committee's accepted foods.

**NOT ACCEPTABLE**

**WARFIELD ENERGIZED PURE COCOA  
WITH VITAMIN B ADDED**

The Warfield Chocolate Company, Chicago, submitted to the Committee on Foods a powdered cocoa mixed with a small amount of dried yeast, called "Warfield Energized Pure Cocoa with Vitamin B Added."

**Discussion of Name and Label**—The label carries the following statements

Warfield's Energized Pure Cocoa with Vitamin B Added is high quality rich cocoa made better by the addition of vitamin B the energy building element. Thus to the natural nutritive qualities of expertly made fine cocoa we have added by a special process an element which makes it even more healthful for drinking baking and cooking.

The name "Energized Cocoa with Vitamin B Added" deceptively suggests that the product contains more "energy" than usual cocoa and that vitamin B per se has been added instead of a small quantity of dried yeast containing some vitamin B. The added dried yeast should be declared in conjunction with the name "Cocoa." Vitamin B is not an "energy building element," does not "give energy," nor is it a "chemical element" as implied. The small amount of yeast ingredient containing vitamin B does not make the product "more healthful," implying a positive promotion of health, nor does it increase the vitamin B content of the cocoa enough to warrant prominent vitamin B claim for the product.

The name and label are grossly deceptive in that they falsely imply that the food article has unusual nutritional or therapeutic "health giving" properties and a high vitamin B content. The company was informed of the opinion of the Committee, but has not demonstrated that steps have been taken to revise the name and label to make them appropriate and truthful. This product will therefore not be listed among the Committee's accepted foods.

**ACCEPTED FOODS**

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION, AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG Secretary

**MALDEN BRAND PURE EVAPORATED MILK**

**Distributor**—Northern Products Company, Inc., Malden, Mass.

**Packer**—The Defiance Milk Products Company, Defiance, Ohio.

**Description**—Canned unsweetened sterilized evaporated milk, the same as Defiance Pure Evaporated Milk, THE JOURNAL, March 3, 1934, page 693.

**HIGH UP BRAND CRYSTAL WHITE SYRUP**

**Distributor**—The Guymon-Petro Mercantile Co., Dodge City and Hutchinson, Kan.

**Packer**—The Hubinger Company, Keokuk, Iowa.

**Description**—Table syrup, corn syrup flavored with sucrose syrup and vanilla extract. The same as Hubinger Crystal White Syrup, THE JOURNAL, Jan 27, 1934, page 293.

**Claims of Manufacturer**—Recommended for use as an easily digestible and readily assimilable carbohydrate supplement to milk in infant feeding and as a syrup for cooking, baking and the table.

**KEYSTONE BRAND EVAPORATED MILK**

**Distributors**—(1) United Wholesale Grocery Company, Pottsville Pa., (2) Sunbury Wholesale Grocery Company, Sunbury, Pa.

**Packer**—The Page Milk Company, Merrill, Wis.

**Description**—Canned unsweetened sterilized evaporated milk, the same as Page Brand Evaporated Milk (Sterilized, Unsweetened), THE JOURNAL, May 30, 1931, page 1872.

## VITAMIN D AND CALCIUM IN FOODS

The efficacy of the commonly used sources of vitamin D in the cure and prevention of infantile rickets has led to the tacit assumption that it would be well from the nutritional point of view to add this food factor to the diet of all persons. This suggestion has not escaped adverse comment. However, the attention given to the vitamin D potency of cod liver oil and halibut liver oil with viosterol, and of egg yolk and liver has raised the question of the efficacy as anti-rachitic and mineralizing agents of some common foods less widely heralded in this respect. Kohman, Sanborn, Eddy and Gurin<sup>1</sup> have called attention to the paucity of information on this point and reported the results of an experimental study.

A mixture of five commercially canned foods—sweet potatoes, spinach, peas, carrots and roast beef—was chosen as more or less similar to an ordinary human diet. To this ration was added calcium lactate until the content of calcium and phosphorus as well as the ratio of one to the other was similar to that of the well known Steenbock rachitogenic ration. When this diet was fed to laboratory animals, it was found that the proportion of ash in the bone was influenced little, if any, by the addition of vitamin D in the form of cod liver oil, indicating that in ordinary foods there is an adequate amount of this factor even for the needs of young growing animals. That vitamin D was present in this diet in significant concentration was then shown by mixing the food mixture in equal parts with the severely rachitogenic diet of Steenbock, here again addition of cod liver oil exerted little influence on the percentage of bone ash.

A further study having a bearing on the foregoing observation was carried out. Several generations of experimental animals were given three diets: a mixture of raw foods, the same after so-called home cooking, and a similar mixture after having been canned (commercially). The reproduction, including consideration of birth and weaning weights of the young, was def-

initely superior in the group given the cooked and canned foods. Furthermore, the young fed the canned food grew far better than those given the raw diet. The authors are inclined to attribute the favorable effect of cooking to the change produced in the cellulose, thus preventing it from absorbing calcium, which would then be lost in the feces. There is no doubt that, when milk is added to both the raw and the cooked food, there is a definite increase in bone ash on all three diets and the differences between raw and cooked foods is eliminated.

These observations indicate again that in foods chosen to be generally representative of our national dietary there is an appreciable lack of calcium. However, the deleterious influence of indigestible residue on calcium absorption can be largely overcome by providing an additional source of this mineral element in readily available form. Furthermore, it appears that in ordinary dietary mixtures chosen in conformity with modern precepts of nutrition there are present adequate amounts of the appropriate accessory food factors for the promotion of satisfactory utilization of calcium and phosphorus.

## COMMON COLDS AND THE WEATHER

Analysis of the factors influencing the so-called common cold are exceedingly complex. Even when attempts are made to correlate the respiratory attack rate with weather variations alone, much difficulty is encountered in dissociating the "weather" components.

Smiley<sup>1</sup> in 1926 reviewed twelve years of monthly records of illness available for 4,000 male students of Cornell University. He found that the peak months for acute respiratory infection, year after year, were December, January, February and March. Of these months, January most commonly carried the peak, four times out of twelve. Just how season was related to incidence of acute respiratory infections was not so clear. He plotted the curves of acute respiratory infections over this period against the mean temperature curves and arrived at a relationship roughly reciprocal. By plotting the average daily precipitation for each month against the average number of acute respiratory infections per school day for that month, only an indefinite relationship between the two was shown. When the average daily hours of sunshine for each month were plotted against the average number of acute respiratory infections per school day for that month, a roughly reciprocal relationship as definite as that between temperature and respiratory infections was obtained. He therefore concluded that apparently there was a definite reciprocal relationship between the incidence of the acute respiratory infections and the mean outside atmospheric temperature. There seemed to be also a relationship between the respiratory infections and the average daily hours of sunshine.

<sup>1</sup> Kohman E F, Sanborn N H, Eddy W H and Gurin C Z. *J Indust & Engin Chem* 26: 758 (July) 1934.

<sup>1</sup> Smiley D F. Seasonal Factors in the Incidence of the Acute Respiratory Infections. *Am J Hyg* 6: 621 (Sept.) 1926.

More recently a further attempt to analyze the weather conditions in relation to the common cold has been published by Gover and her co-workers.<sup>2</sup> The complicated nature of the problem is well recognized by these workers, who say

Because summer and winter, in terms of meteorological conditions, are a composite expression of many varying factors, the problem of relating the incidence of disease to atmospheric conditions is a complicated one. It is obvious that the mere increase in mortality in the fall and winter when there is a decrease in the hours of sunshine cannot be assumed to express any causative relationship. The same is true of temperature and other weather conditions that may, on closer examination, be found to be associated with the incidence of respiratory diseases. Aside from the fallacy of assuming causative relationship, it cannot be assumed that there is any very close association between such variables as respiratory disease incidence and temperature or hours of sunshine until the usual or normal seasonal variation has been eliminated from the picture. So many weather conditions show the same seasonal swing that any one or all might appear to be closely correlated with respiratory affections unless examined apart from seasonal variation.

The data used in this study were obtained from a survey made on the weekly incidence of respiratory disorders among students in various universities of the United States in a period of eighteen months from November 1923 to April 1925. The six university groups comprising the study were well distributed geographically: Boston, Washington, D. C., Columbus, Ohio, Chicago, New Orleans, and Berkeley, Calif. Weather conditions with respect to mean temperature, daily temperature range, relative humidity, absolute humidity, hours of sunshine, wind velocity, precipitation, and the respiratory attacks were considered in weekly intervals. A full twelve months period was also presented to give a climatic background for each city. An examination of the weather variables by statistical methods did not reveal any close association between the magnitude of the respiratory attack rate and weather conditions, though there was a tendency to slight association of some of the items. Thus, for the year ended May 2, 1925, in each city except Boston, the attack rate showed a small negative correlation with the mean temperature. This appears to be statistically significant as judged by its probable error. Daily temperature range, however, showed a significant correlation in only one of the cities. It was concluded that no definite association of respiratory attack rates with marked variations in climate could be determined. Weekly deviations from the "norm" of the respiratory attack rate showed a small association with deviations from the "norm" in mean temperature for the corresponding week and also for the preceding week. A respiratory attack rate above normal was associated with a mean temperature below normal, this association was higher during the early fall months than at any other time of the year.

It has been difficult to collect reliable information of the incidence of respiratory disturbances in relation to

weather conditions on a large enough number of persons to have significance. Climatic and geographic distribution has also been difficult to obtain, but, as the most extensive study so far made on the subject, the report of Gover and her collaborators offers some corroboratory basis for the common impression that "colds" are more frequent in cold weather.

#### SPONTANEOUS RECOVERY IN MESENTERIC VASCULAR OCCLUSION

The prognosis in superior mesenteric thrombosis usually is gloomy. Occasionally, however, recovery occurs following surgical intervention, or it may be spontaneous. Sargent<sup>1</sup> recently reported the case of a man, aged 74, who suddenly had intense pain in the upper part of the abdomen above and to the left of the umbilicus. The abdomen was tender on palpation over this area and slightly rigid. He gave no account of previous attacks of abdominal disease. Soon after admission to the hospital, the patient passed a stool suggestive of melena. A diagnosis of partial intestinal obstruction was made and a laparotomy was performed. About four feet of the ileum was found to be dilated and of a dark plum color. The blood vessels in the mesentery felt like thickened cords, and nowhere did they pulsate. In view of the patient's age and the amount of tissue involved, an attempt at resection was not made and the abdomen was closed. The patient was gravely ill for several days, but a week after the operation the hiccups, vomiting and pain suddenly ceased and a normal stool was passed. In another week the patient had almost completely recovered. The facts in this case apparently fit a diagnosis of superior mesenteric thrombosis, although the condition may have been volvulus, as was suggested to the author.

Mesenteric vascular occlusion may arise following some abdominal infection, particularly appendicitis, or it may be the result of some disease of the circulatory system, such as arteriosclerosis, endocarditis, phlebitis or aneurysm. The absence of an infectious etiology is a favorable factor. In view of the history it seems that the case described by Sargent was not the result of infection. In 1931 Meyer<sup>2</sup> reviewed the literature on mesenteric vascular occlusion for the previous ten years and found that ninety-two proved cases had been reported. Among these cases were nine instances of spontaneous recoveries. An exploratory operation alone was done seventeen times, and six of the patients recovered. There were forty-three cases in which resection was done, followed by a mortality of 32.6 per cent. Three patients recovered following almost complete removal of the small intestine.

In THE JOURNAL<sup>3</sup> recently was reported the case of a man, aged 60, who had a sudden mesenteric throm-

basis, which was not associated with any previous abdominal complaints or with infective process. He was operated on about five hours after the onset of symptoms, and about two and a half feet of the small intestine was resected. The favorable result in this case may have been due to the early operative intervention.

## Current Comment

### STANDARDS OF PRENATAL CARE

In February the Children's Bureau published a revised pamphlet<sup>1</sup> containing the minimum professional care which, in the opinion of the advisory committee, pregnant women should receive. The first edition of these standards was issued in 1925, at which time it was recognized that if all the requirements considered desirable or necessary by a number of different specialists were included, the material would be too bulky to be of use to the medical profession. As a result of intelligent compromise, an outline has been produced that includes essentials of past history, obstetric history, physical and laboratory examinations, and instructions to patients, which fills only four pages. In this edition the only change has been the addition of the hemoglobin test to the physical examination. As a guide, especially to those not specializing in obstetrics, this pamphlet should be particularly useful. In view of the widespread interest in and comment on maternal mortality, it would seem that every physician would desire to be at least as thorough as the suggestions of the outline. It seems probable, in recognition of the published analyses of the causes of maternal deaths, that thoroughness of prenatal care alone would have some effect on the number of maternal deaths.

### THE LEGION AWARD CITATION TO WILLIAM AND CHARLES MAYO

The citation by the American Legion of Drs. William J. and Charles H. Mayo for distinguished public service, with the award made by the President of the United States in person, is a great honor for American medicine. It has been said that opportunities and great occasions make men. An exception to this rule is presented in the work and life of these distinguished medical leaders. They have made a small village become one of the notable medical centers of the world wholly through a genius for surgery and for medical leadership. Throughout their careers they have devoted themselves to the advancement of organized medicine. The medical society of the county in which they practice was founded by their father. Both have been presidents of the American Medical Association. In 1906, when Dr. William J. Mayo delivered his presidential address to the American Medical Association, he forecast and considered some of the hazards that concern medical practice today. He attacked the abuse of medical care by public service corporations and the

abuses of public charity and of private institutions by those able to pay, and he condemned all systems of hospital and medical care dominated by laymen. He concluded his address with a plea for harmony in the medical profession, recognizing that only a strongly united opinion could gain for medicine the place in our civilization which it merits. Recognizing their leadership, their service to mankind and the spirit that has motivated Drs. William J. and Charles H. Mayo throughout their long and successful careers, *The Journal* congratulates the American Legion on bestowing its highest honor where that honor is so fully deserved.

### UREA AND ECONOMY OF WATER

Of the manifold recognized functions of the kidney, the one among the earliest to be recognized and, perhaps, most to be taken for granted is that of concentration. Urine contains nothing new, all its constituents, with the probable exception of ammonia, appear preformed in the blood. The renal apparatus does, however, excrete these solutes in much higher concentration than exists in the blood, with a resultant conservation of water. This activity of the kidney has recently been given quantitative expression by Gamble and his associates<sup>1</sup> at the Harvard Medical School. By equating the concentration of substance under investigation in the diet of experimental animals with that in the urine, the amount of water withdrawn per unit of solute was determined. The unit of solvent employed was the osmumol, so that direct comparisons could be made on the basis of osmotic pressure. The ions  $\text{Na}^+$ ,  $\text{K}^+$ ,  $\text{Cl}^-$ ,  $\text{HCO}_3^-$ ,  $\text{H}_2\text{PO}_4^-$  and  $\text{SO}_4^{=}$ , with urea, creatinine, dextrose and galactose, were used alone and in pairs. It was observed that, for all the substances examined except urea, the water requirements established for the individual solutes can be added together when the substances are used in mixtures to predict the observed values. In the case of urea, however, much less water is excreted than would be expected from the individual values. The conservation of water is a prime necessity for terrestrial animals, and urea for mammals at least, is the leading metabolic waste product. There is in this combination of circumstances a peculiarly effective mechanism, one of a multitude of such whereby the higher organism is adjusted to its environment.

## Association News

### MEDICAL BROADCASTS Columbia Broadcasting System

The American Medical Association broadcasts on a Western network of the Columbia Broadcasting System each Thursday afternoon on the Educational Forum from 4:30 to 4:45, Central daylight saving time. The next three broadcasts and the speakers will be as follows:

August 16	Black Widow	W. W. Bauer, M.D.
August 23	Infantile Paralysis	W. W. Bauer, M.D.
August 30	Your Child Enters School	Morris Fishbein, M.D.

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION PUBLIC HEALTH ETC)

### CALIFORNIA

**Plague-Infected Rodents in Modoc County**—According to *Public Health Reports*, plague-infected ground squirrels have been found in Modoc County as follows: June 26, six, July 5, one, and July 9, one.

**Restriction on Manufacture of Convalescent Serum**—In view of the recent death of a child and the severe illness of another from the prophylactic use of human serum against infantile paralysis, the state department of health issued a regulation restricting the manufacture and distribution of human convalescent serum to laboratories that are approved by the state board of health. This applies to the equipment, training of personnel, technique and process of manufacture of the serum by public and private laboratories. The regulation is effective for sixty days, beginning June 27.

**Immunization Campaign**—An immunization campaign against diphtheria and smallpox will be conducted for six weeks in San Francisco with the opening of schools, under the auspices of the San Francisco County Medical Society and the city department of health. A campaign was inaugurated August 6, to acquaint the public with the objectives of the plan. Physicians have agreed to immunize free of charge all those who cannot pay, the health department furnishing the vaccine and toxoid. The department will also furnish cards to physicians for reporting the completion of each immunization and vaccination. Cards for reporting Schick tests will be issued after six months. Physicians will follow up their own patients for return appointments for injections of toxoid and vaccine but will return to the department of health the cards of those who fail to return after a period of four weeks. The department will then attempt to have the patient return to the physician. The department will also notify each patient to return to his physician when the Schick test is due. Hours during which this special immunization is done will be left to the convenience of the physician.

### COLORADO

**Personal**—Dr. George H. Curfman, Salida, received the merit award of the Northwestern University Alumni Association on "illumination night" in Evanston, preceding the annual commencement, June 15. The award is given annually to alumni for "worthy achievement which has reflected credit upon their alma mater."—Dr. Benjamin E. McBrayer, Arvada, was named health officer of Jefferson County, succeeding the late Dr. Richard Russell.

### FLORIDA

**Dengue Fever in Miami**—Eighty cases of dengue fever were reported in Miami, according to the *New York Times*, July 31. Special efforts are being made to control the spread of the disease by eradicating mosquitoes.

**Society News**—At the semiannual meeting of the Central Florida Medical Association in Leesburg, June 8, speakers included Drs. Gaston H. Edwards, Orlando, and Edwin H. Andrews, Gainesville, on "Treatment of Chronic Pelvic Infections" and "Use and Abuse of Urinary Antiseptics" respectively.—Speakers before the Dade County Medical Society in Huntington, July 6, were Drs. Michael P. DeBoe, Miami, on hobbies, and Mathew Jay Flipse, Miami, on agranulocytosis.—A symposium on the urinary tract in infancy and childhood constituted the program of the Duval County Medical Society in Jacksonville, June 5. Speakers were Drs. Elijah T. Sellers, Robert B. McIver, W. M. Shaw and Luther W. Holloway.

### ILLINOIS

**Appointed Dispatch Secretary to Virgin Islands**—Dr. Arthur I. Edison Maywood has been appointed resident medical officer and government secretary of the island of St. John, Virgin Islands, with the title of dispatch secretary. Dr. Edison sailed for the island July 5. In addition to other duties he plans to engage in medical research. Dr. Edison was formerly health officer of Broadview and Westchester.

**Sale of Food Banned at Circus**—During the appearance of the Ringling Brothers-Barnum and Bailey Circus in Evanston, beginning August 2, the sale of food on the show grounds was banned by health authorities, on account of the recent outbreak of typhoid among performers. The disease was believed to have been contracted in New Castle, Pa. One death occurred in Dayton, and another in Detroit (*THE JOURNAL*, August 4, p. 350).

### CHICAGO

**Dr. Gellhorn Awarded Alvarenga Prize**—Dr. Ernst Gellhorn, professor of physiology, University of Illinois College of Medicine, was awarded the Alvarenga Prize for 1934 for his essay entitled "The Influence of Parathormone on the Neuromuscular System: An Experimental Analysis." The prize, amounting to about \$300, is awarded by the College of Physicians of Philadelphia.

### INDIANA

**State Board Election**—Dr. Edmund M. Van Buskirk, Fort Wayne, was elected president of the Indiana State Board of Health, July 16, at a meeting in the State House, Indianapolis. Other members of the board are Dr. Verne K. Harvey, Indianapolis, secretary, reelected; Dr. Ernest Rupel, Indianapolis, vice president, and Dr. John C. Glackman, Rockport, the retiring president. Dr. Van Buskirk served for many years as health officer of Allen County.

**Books Given to Hospital**—Sixty medical books were recently given to Indianapolis Methodist Episcopal Hospital by Mrs. John Henry Eberwein, Indianapolis. The books belonged to her father, Dr. J. B. Clark, who practiced medicine for more than fifty years in Economy. Included among them is a series of lectures given before the medical students in the University of Pennsylvania in the year 1859. Dr. Clark won this book, autographed by the author, as a prize the year he graduated. Dr. John William Hofmann recently presented the hospital's library with fifty volumes, and Dr. Robert O. McAlexander with thirty, together with about 250 medical magazines. Dr. David H. Sluss has also donated books recently.

### IOWA

**Annual Clinic**—The Iowa County Medical Society sponsored its third annual heart and chest clinic at Marengo, June 22. Dr. F. M. Smith of the University of Iowa College of Medicine and Dr. John H. Peck, Des Moines, president of the Iowa Tuberculosis Association, conducted the clinic. Physicians were privileged to designate patients for examination, these being visited in advance by a nurse to obtain the history. A banquet was held preceding the clinic. Dr. Smith discussed "Treatment of Heart Disease," and Dr. Peck, "Our Responsibility in Pulmonary Tuberculosis."

**Society News**—Dr. Marvin Sukov, Clarinda, among others, addressed the Southwestern Iowa Postgraduate Medical Association in Clarinda, June 7, on "Current Concepts of Schizophrenia."—Dr. Furman P. Ralston, Knoxville, was elected president of the Des Moines Valley Medical Association at its sixty-first annual meeting in Ottumwa, June 18, and Dr. Edward B. Hoeven, Ottumwa, was reelected secretary.—The Grundy County Medical Society was host to the Sixth Council District Medical Society, July 5, speakers included Drs. Milford E. Barnes, Iowa City, on "Application of Preventive Medicine to the Public Milk Supply," and Ransom D. Bernard, Clarion, "Proposed Basic Science Law."

### KENTUCKY

**Personal**—Dr. Edward T. Thompson, formerly administrator of Indiana University School of Medicine, Indianapolis, has been appointed superintendent of Norton Memorial Infirmary, Louisville.—Dr. Robert K. Galloway, Henderson, director of the Henderson County health department for four years, has been appointed assistant to the director of county health work of the state board of health.

**Society News**—Drs. William O. Floyd and Milton Smith Lewis, Nashville, addressed a joint meeting of the Todd and Christian county medical societies at Trenton, July 19, on "Management of Hernia" and "Factors That Influence Infant Mortality in the First Month of Life," respectively.—Dr. Irvin Abell, Louisville, addressed the Henderson County Medical Society, Henderson, recently, on cancer of the uterus.

**University News**—The bacteriologic laboratory of the city of Louisville has recently been amalgamated with the bacteriologic laboratory of the Louisville City Hospital, which is affiliated with the University of Louisville School of Medicine, with James A. Kennedy, Ph.D., recently of the University of

Georgia School of Medicine, as director Dr Harry S Andrews, instructor in pediatrics at the medical school, has been made director of service at the Children's Free Hospital, also affiliated with the school. Recent promotions at the university include

Dr Alice N Pickett associate professor of obstetrics  
Dr William T McConnell associate clinical professor of obstetrics  
Dr William O Johnson assistant clinical professor of gynecology

### LOUISIANA

**Personal**—Dr Oscar W Bethea, professor of clinical medicine, Tulane University of Louisiana School of Medicine, New Orleans, was awarded the honorary degree of master of pharmacy by the Philadelphia College of Pharmacy and Science at its one hundred and twelfth commencement, June 6. Dr Bethea delivered the commencement address.

### MARYLAND

**Model Health Unit Discontinued**—With the withdrawal of the Johns Hopkins School of Hygiene and Public Health and the Rockefeller Foundation from participation in the model health department in Anne Arundel County on the expiration of their agreement, July 31, the unit was abandoned. Established in 1931, the department was cooperatively maintained by the foundation, the school and the county and state health departments, to work out programs of preventive medicine with particular emphasis on sanitation problems. Anne Arundel County was selected because of its large population, its proximity to Baltimore, and the complicated health problems created by its many rivers and shore lines. Activities of the unit will be absorbed by the public health district instituted in 1932 in accordance with a recommendation of Dr Joseph Mountain in his public health survey of Baltimore. This district includes the sixth and seventh wards and was created to make the residents the subject of medical experimentation in the public health field. A grant of about \$25,000 for two or more years by the Rockefeller Foundation, through the school of hygiene and public health, provides for the training of public health workers. These institutions, it was stated, saw no reason for continuing their partial support of the Anne Arundel unit when the city health center can serve their purposes more conveniently and without duplication of expenditures. The county's activities will be taken over by the state and county health authorities.

### MINNESOTA

**State Medical Election**—Dr William A Coventry, Duluth, was elected president of the Minnesota State Medical Association at its annual meeting in Duluth, July 15-18, to take office in January. Dr Alfred G Chadbourn, Heron Lake, and Dr E Sydney Boleyn, Stillwater, were named vice presidents, and Drs Edward A Meyerding, St Paul, and William H Condit, Minneapolis, reelected secretary and treasurer, respectively. The next annual session will be held in Minneapolis.

### MISSOURI

**Heat Wave Causes High Death Rate**—Telegraphic reports to the U S Department of Commerce from eighty-six cities with a total population of 37 million, for the week ended July 28, indicate that the highest mortality rate (34) appears for St Louis and that the rate for the group of cities as a whole was 12.3. The unusually high death rate was attributed to the prevailing heat wave. Other high rates were for Cincinnati, 32; Omaha, 29; Kansas City, Mo., 26.2; Indianapolis, 23.9; and Memphis, 21.6. The mortality rates for these cities for the corresponding weeks of 1933 were: St Louis, 13; Cincinnati, 14.6; Omaha, 9; Kansas City, 11; Indianapolis, 12.1; Memphis, 21. The annual rate for eighty-six cities was 11.9 for the thirty weeks of 1934 as compared with 11.3 for the corresponding period of 1933. Caution should be used in the interpretation of these weekly figures as they fluctuate widely. The fact that some cities are hospital centers for wide areas outside the city limits or that they have large Negro populations may tend to increase the death rate.

### NEW JERSEY

**New Translation of Galen Found at Princeton**—In the course of cataloguing a collection of Arabic manuscripts on deposit in the library of Princeton University, Princeton, a translation of the treatises of Galen from Greek into the Arabic has been discovered. It was recently reported. The translation, made by Hunayn Ibn-Ishaq, bears the date 1774, according to newspaper accounts.

**Epidemic of Bacillary Dysentery**—More than 100 persons have been stricken in an epidemic of bacillary dysentery, which began in Jersey City, July 21. Five deaths have occurred among children. The health department, the Red Cross and other agencies have sent nurses into the homes of victims to give instruction in sanitation and preparation of food. The capacity of the isolation wards of the Jersey City Medical Center is said to be practically exhausted, with sixty-six cases, and efforts were being made to obtain additional room at the Essex County Hospital for Contagious Diseases, Belleville, according to the *New York Times*.

### NEW MEXICO

**Personal**—Dr William W Peter, White Plains, N Y, who for years engaged in health work in China, has been appointed medical director for the Navajo Indian Reservation.

**State Medical Election**—Dr Charles W Gerber, Las Cruces, was named president-elect of the New Mexico Medical Society at the annual meeting in Las Vegas, July 20. Dr Charles F Milligan, Clayton, became president and Drs George W Jones, Clovis, and Lea B Cohenour, Albuquerque, vice president and secretary, respectively. The 1935 meeting will be held in Albuquerque in May.

**Public Health Meeting**—The New Mexico Public Health Association held its annual meeting in Las Vegas, July 17-18. Guest speakers were Carl E Buck, Dr P H, New York, who recently made a health survey of the state, Dr Gerrit Heusinkveld, Denver, who discussed training of midwives, and Dr John W Brown, health officer of Texas, Austin. Dr Buck also discussed the health survey at a public health meeting at Ifield Auditorium, New Mexico Normal University.

### NEW YORK

**Scarlet Fever Following Picnic**—Twenty cases of scarlet fever were reported in the village of Catskill following a picnic, June 29. In three cases the illness began the next day and the others set in July 2 and 3. Both adults and children were attacked. All cases are said to have been mild. The state health department is conducting an investigation in cooperation with the local health officer, Dr William M Rapp.

### New York City

**Illegal Practitioner Given Suspended Sentence**—Mrs Winifred Danielson, Brooklyn, pleaded guilty to illegal practice, July 9, in the court of special sessions and was sentenced to six months in the workhouse, July 19. The sentence was suspended pending good behavior. Mrs Danielson was arrested last March on the complaint of two inspectors for the state department of education.

**Health Center Accepted by City**—The East Harlem Health Center, founded in 1921 by the New York chapter of the American Red Cross, was presented to the city, June 21. Mayor La Guardia was present. Dr Livingston Farrand, president of Cornell University, Dr John L Rice, health commissioner and Homer Folks, secretary of the State Charities Aid Association, gave addresses.

**Personal**—Dr Julius J Valentine was recently decorated by the government of Venezuela for services rendered to that country. Dr Valentine is a past president of the Pan American Medical Association. Dr Raymond B Allen, associate director, New York Post-Graduate Medical School, has been appointed associate dean in charge of graduate studies at Columbia University College of Physicians and Surgeons. Dr Joseph W Miller has recently been reappointed an honorary consulting surgeon to the New York City Police Department. Dr Jacob J Golub sailed for Europe, July 5, on his way to spend two months as consultant to the Hebrew University in Palestine in connection with the building of the Hebrew University Hospital in Jerusalem.

**Social Workers Stationed in Courts**—The experiment of having social workers stationed in magistrates' courts as advisers in mendicancy cases, sponsored by the Welfare Council of New York, will be continued as a regular function of the department of public welfare, it was recently announced. Of the number of mendicants examined it was said that 58 per cent were alcoholic addicts, 12 per cent were drug addicts, 22 per cent had venereal diseases and 15 per cent were mentally impaired. The majority were more than 40 years old and unmarried. After arrest and conviction the beggars are examined by a physician and a report is laid before the magistrates to assist him in deciding on appropriate action. Many professional beggars have been exposed, the sick have been sent to health and welfare agencies, and those who resorted to begging because they were ignorant of sources of aid have been helped through relief channels.

## NORTH CAROLINA

**Society News**—A symposium on cancer was presented before the Buncombe County Medical Society, Asheville, June 18, by Drs. James M. Lynch, Charles S. Norburn and George Curtis Crump. Dr. Walter R. Johnson addressed the society, June 4, on cancer of the stomach.—Dr. Merle D. Bonner, Jamestown, spoke on medical and surgical treatment of tuberculosis before the Guilford County Medical Society, Greensboro, June 7.—Speakers before the final meeting for this season of the Mecklenburg County Medical Society, Charlotte, June 19, were Drs. Andrew J. Crowell, on "Diagnosis and Treatment of Malignancies of the Prostate," Oren Moore, "Inversion of the Uterus," and James W. Gibbon, "Operative Treatment of Cancer of the Rectum."

## OHIO

**Hospital News**—A plaque was presented to Charity Hospital in Cleveland, June 20, during the annual meeting of the Catholic Hospital Association of the United States and Canada honoring the institution as the oldest hospital in the city.—The Good Samaritan Hospital, Cincinnati, closed its outpatient clinic, June 30, because of financial stringency, it is reported.—St. Alexis Hospital, Cleveland, celebrated the fiftieth anniversary of its founding, July 17-19. The hospital has cared for 74,291 patients in the half century, it was announced.

**Society News**—Speakers at the annual meeting of the eighth district of the Ohio State Medical Association in McConnelsville, June 21, were Drs. Verne A. Dodd, Columbus, on "Surgical Aspects of Ulcers and Cancer of the Stomach", Arthur G. Helmick, Columbus, "Nutritional Facts and Facts from the Viewpoint of the Clinician", James M. Appel, North Royalton, "Collapse Therapy in Tuberculosis", Reo M. Swan, Cambridge, "Amebic Dysentery," and Harry E. LeFever, Columbus, "Intracranial Hemorrhage."—Dr. Samuel J. Ellison, West Union, among others, addressed the Adams County Medical Society, West Union, June 27, on prevention of scarlet fever.—Drs. Harry H. McClellan, Dayton, and George B. Faulder, Wapakoneta, addressed the Auglaize County Medical Society, July 12, at Wapakoneta, on "Physical Causes of Nervous and Mental Diseases" and "Version versus Forceps," respectively.—The Ohio State Medical Association is preparing a series of study outlines for the use of county societies as suggestions for program material. The first two, dealing with scarlet fever and peritonitis, appeared in the August issue of the *Ohio State Medical Journal*.

## OREGON

**Eyesight Swindlers**—The Oregon state police recently reported that two men, using methods varying only slightly from others previously mentioned in THE JOURNAL, had swindled a Mr. and Mrs. Joseph Aubel, Grants Pass, out of \$912.50 by promising to cure Mr. Aubel's eyes with radium. They assured Mr. Aubel that radium would cure his eyes in twenty-one days the cost to be \$412.50. That amount was paid with an additional \$500 for the rental of a so-called radium belt, which was represented to be a positive cure for diabetes. The latter sum was to be refunded in twenty-one days. One man who called himself Dr. Miles was about 45 years old, 5 feet 9 inches tall, of stocky build and weighing about 170 pounds, smooth shaven, believed to be of Italian extraction. The other was slender, had a long face and light complexion, light hair and blue eyes, freckled face and hands. THE JOURNAL, March 17, page 849 printed a similar report, in which one man gave the name Dr. Miles, Concord and Grove Avenues, Chicago, a fictitious address.

## PENNSYLVANIA

**Society News**—Dr. John W. Shirer, Pittsburgh, addressed the Somerset County Medical Society, Johnstown, July 18 on the mortality of appendicitis.—Dr. Max Levin, Harrisburg, addressed the Cumberland County Medical Society, Carlisle, July 10, on medical aspects of mental hygiene.

**Personal**—Dr. Donald Guthrie Sayre, president of the Medical Society of the State of Pennsylvania, has recently been elected to membership in the Royal Academy of Medicine in Rome.—Dr. William H. Kunsman, Morrisville, recently celebrated the fiftieth anniversary of his entrance into medical practice.

## Philadelphia

**Personal**—Dr. Charles F. Nassau has been appointed honorary president of the John Chalmers Da Costa Foundation. The late Dr. William W. Keen formerly held this office.—Dr. Charles H. Frazier was recently elected a member of

the board of trustees of the University of Pennsylvania.—Dr. Harry Z. Hibshman was promoted from clinical professor to professor of proctology at Temple University School of Medicine, June 1.

## TENNESSEE

**Compulsory Inspection of Automobiles**—A system of compulsory mechanical inspection of automobiles introduced last April in Memphis is credited with a 25 per cent reduction in deaths from automobile accidents as compared with the number for 1933. Brakes, lights, windshield wiper, steering and wheel alignment are to be tested every six months, according to the new arrangement. If a car fails to pass inspection, seven days is allowed for the owner to have repairs made. On the first test, only 28,340 of the 48,500 automobiles in Memphis passed the inspection, but a report published in June stated that 44,914 vehicles had received the sticker of approval.

**Society News**—Drs. Edward T. Newell and Walter G. Bogart, Chattanooga, addressed the Hamilton County Medical Society, August 9, on "Irradiation and Cautey Excision in the Treatment of Malignancies" and "The Past Fifty Years in Medicine," respectively.—At a meeting of the Hardin-Lawrence-Lewis-Perry-Wayne Counties Medical Society in Waynesboro, June 26, speakers were Drs. J. T. Keeton, Clifton, on hypertension, Nathaniel S. Shofner, Nashville, hyperthyroidism, James Frazier Binns, Nashville, diarrhea, and James V. Hughes Jr., Savannah, rat bite.—Drs. Martin E. Blanton and Edward M. Fleener, Johnson City, addressed the Washington County Medical Society, August 2, on "Injuries to the Eye" and "Early Diagnosis of Appendicitis in Children," respectively.—Drs. Arthur G. Quinn and Otis S. Warr, Memphis, addressed the Tri-County Medical Association (Henderson, Decatur and Chester counties), Henderson, June 14, on "Feeding of the New-Born Infant" and "Diseases of the Colon," respectively.

## TEXAS

**Personal**—Dr. William W. Dunn has been appointed health officer of Beaumont.—The Venezuelan medal of honor was recently conferred on Dr. John O. McReynolds, Dallas, in recognition of his services to the cause of education "as a mark of the gratitude of the people of Venezuela."

**Society News**—Dr. Stuart T. Wier, Beaumont, among others, addressed the Jefferson County Medical Society, Port Arthur, June 11, on "Amputation of the Forearm under Local Anesthesia."—Dr. Ray M. Balyeat, Oklahoma City, addressed the Grayson County Medical Association, June 12, on diagnosis and treatment of allergic conditions.—At a meeting of the Twelfth District Medical Society at Hillsboro, July 10, speakers included Drs. Titus H. Harris, Galveston, on "Psychiatry as Related to Medicine in General", Leslie E. Kelton Jr., Corsicana, "Amebiasis," and Roy G. Giles, Temple, "Roentgen Therapy in Carcinoma of the Breast."

## VERMONT

**Society News**—The annual meeting of the New England Surgical Society will be held at Burlington, September 28-29.—Dr. George R. Eades, Keene, N. H., addressed the Windham County Medical Society, Brattleboro, June 13, on acute otitis media.—Dr. Clarence A. Bonner, Danvers, Mass., addressed the Windsor County Medical Society, Windsor, May 17, on "Modern Trends in the Treatment of the Insane."—At the quarterly meeting of the Northeastern County Medical Society, Barton, in May, Dr. Fraser B. Gurd, Montreal, delivered an address on "Rectal Conditions as Met by the General Practitioner."

## WEST VIRGINIA

**Society News**—Maj. Gen. Harry L. Gilchrist, Washington, D. C., addressed a joint meeting of the Ohio County Medical Society and the Fort Henry chapter, Reserve Officers Association in Wheeling, in May, on chemical warfare.—Drs. Frederick R. Whittlesey, Morgantown, and Justus C. Pickett, Pursglove, addressed the Monongalia County Medical Society, Morgantown, June 5, on heart disease and disability resulting from injuries to the vertebral column, respectively.

**Sterilization Law to Be Enforced**—A law authorizing sterilization of inmates of various state institutions gives heads of those institutions the right to petition the Public Health Council for permission to enforce the law, according to a ruling handed down by the council at a meeting July 11. The sterilization law was passed in 1929 but has never been enforced because of certain details that have not been sufficiently studied, it was said. The ruling paves the way for inaugurating a program of sterilization of the mentally unfit of which there

are reported to be more than 400 in the state. The statute provides for hearings on each case in the county in which the patient resides.

### WYOMING

**State Medical Election**—Dr Joseph L Wicks, Evanston, was named president-elect of the Wyoming State Medical Society at the annual session in Casper, July 16, and Dr Herbert L Harvey, Casper, was installed as president. Dr Chester Harris, Basin, was elected vice president and Dr Earl Whedon, Sheridan, reelected secretary. The 1935 meeting will be held in Lander in June.

### GENERAL

**Society News**—The National Medical Association will hold its annual meeting in Nashville, Tenn., August 13-18, under the presidency of Dr Midian O Bousfield, Chicago. The American College of Physicians will hold its nineteenth annual clinical session in Philadelphia, April 29-May 3, 1935.

**News of Epidemics**—About 150 cases of malaria have occurred in an outbreak in Georgetown County, South Carolina, newspapers reported, July 12.—Nine cases of typhoid with three deaths were reported in Fremont, Ohio, July 6, the source was not determined.—Whooping cough was said to be epidemic in Erie, Pa., with fifty five cases reported in June, as compared with five cases for June, 1933.—Thirty-eight cases of typhoid, with seven deaths, have occurred in Monmouth County, N. J., since May 1, the source has not been definitely determined, but two carriers were found working in food shops.—Twelve persons were reported to be suffering from typhoid in Decatur, Ala., as a result of using water from a contaminated well.

**Financial Aid for College Students**—Twelve per cent of the students of non-profit making colleges will be assisted in earning their way through school during the coming winter through the student aid program of the Federal Emergency Relief Administration, it was recently announced. The number aided will be about 100,000, it is estimated. Last year 10 per cent of the enrolments, or about 75,000 were helped. FERA funds will be allotted through state emergency relief administrations to certain qualifying institutions and paid to the students for part time work on socially desirable projects. It is suggested that medical students may aid in the health work and nutrition projects carried on by the relief administration. L. R. Alderman, director of the educational division of the relief administration, is in charge of the student aid program. Students may earn up to \$20 a month each.

**American Public Health Association**—The sixty-third annual meeting of the American Public Health Association will be held in Pasadena, Calif., September 3-6. The preliminary program includes the following speakers and addresses:

Elmer V McCollum, Ph.D., Baltimore: Nutritional Aspects of Milk Pasteurization.  
Dr Maurice L Tainter and Windsor C Cutting, San Francisco: Use of Dinitrophenol in Nutritional Disorders.  
R. R. Parker, U. S. Public Health Service, Hamilton, Mont.: Rocky Mountain Spotted Fever: Result of Ten Years Prophylactic Vaccination.  
Dr William W Bauer, Chicago: Role of Milk in Diets.  
Dr John E Gordon and G. F. Badger, Detroit, and George B Darling, Jr., Dr P. H. Battle Creek, Mich.: Reaction of Familial Contacts to Scarlet Fever Infection.  
Dr Francis W O'Connor, New York: The Concern of the United States with Tropical Diseases.  
Emery W Dennis, Ph.D., American University of Beirut, Syria: Dysenteries and Diarrheas of Childhood in the Near East.

A symposium on amebic dysentery will be presented by Karl F Meyer, Ph.D., Drs Alfred C Reed and Jacob C Geiger, all of San Francisco, and the subject will also be discussed in a symposium on municipal public health engineering by Joel I Connolly and Arthur E Gorman, Chicago, sanitary engineers. During the four days preceding the association's meeting, Dr Iago Galdston, New York, will conduct the third Institute on Health Education.

### FOREIGN

**Orthopedic Prize**—The Rizzoli Orthopedic Institute in Bologna, Italy, announces the opening of competition for the Umberto I prize of 3,500 lire for "the best orthopedic work or invention." Foreign physicians are invited to submit entries which will be judged by the provincial council of Bologna. Regulations governing the competition may be obtained from the president of the Rizzoli Institute. Entries must be submitted before December 31.

**Tuberculosis Campaign in China**—The National Anti-Tuberculosis Association of China was formed within recent months, with Dr Way S New, Shanghai, as chairman of the

administrative board and with headquarters in the building of the Chinese Medical Association. According to regulations adopted to govern the association, the administrative board is to have fifty-five members and there will also be a supervisory board of eleven members. A general secretary will execute the work of the association, which will have both individual and group memberships.

**Radiologic Institute in Madras**—The Madras Government Institute of Radiology was opened March 26, in connection with the Madras Government General Hospital at Madras. The institute, a two story building, is connected with the surgical block of the hospital and is expected to become an important training center for India. It provides rooms for all types of roentgenologic work, clinical photographic and electrocardiographic departments, a hydrotherapy section, ultraviolet ray center, a radium theater radon laboratory, a radium safe room and halls for remedial exercises and electrical and heat treatments.

**Society News**—The fourth conference of the International Association of Preventive Pediatrics (the medical section of the International Save the Children Union) will be held in Lyons, France, September 27-28. Themes to be considered are prevention of malaria in children and prevention of rickets and spasmophilia. Further details may be obtained from the secretary of the association, 15 rue Levrier, Geneva.—A congress on colibacillosis and other infections and intoxications of intestinal origin will be held September 23-24 at Châtel Guyon, France, under the presidency of Prof. Paul Carnot. This meeting was first announced for May 20-21. The secretary of the congress is Dr Pierre Balme, Societe des Eaux Minerales, Châtel-Guyon.

**Personal**—The honorary degree of doctor of science was recently conferred on Sir Henry Wellcome, head of the Wellcome Research Foundation, London, by Marquette University, Milwaukee.—Dr Samuel E Whitnall, Robert Reford professor of anatomy, McGill University Faculty of Medicine, Montreal, has been appointed professor of anatomy at the University of Bristol, England, to succeed Prof. Edward Fawcett.—Sir Frederick Gowland Hopkins, president of the Royal Society of England since 1931, has been awarded the Albert Medal of the Royal Society of Arts for 1934 "for his researches in biochemistry and the constituents of food." This medal was instituted in 1826 and is awarded annually for merit in promoting arts, manufactures or commerce.—Salvatore Ottolenghi, director of the Italian Scientific Police and professor of legal medicine, University of Rome, died recently, in Rome.

## Government Services

### Veterans' Home to Be Converted to Neuropsychiatric Facility

The Veterans' Administration Home at Danville, Ill., will shortly be remodeled into a neuropsychiatric facility, the administrator of veterans' affairs recently announced. Extensive alterations will provide for an ultimate capacity of 1,800 beds. Heating, plumbing and electrical work will be replaced, fireproof stairways will be built, the dining hall and kitchen building are to be rearranged and repaired, and adequate quarters for personnel will be provided. It is expected that this project will obviate the necessity for additional construction at other neuropsychiatric hospitals in the Middle West.

### U S Public Health Service

Medical Director Claude C Pierce, relieved from duty in the bureau of the public health service, Washington, D. C., and directed to Paris, France, for duty in the office of the American consul general and to assume supervisory charge of service activities in Europe.

Asst. Surg. William H Gordon, relieved at Ellis Island and assigned to duty at the marine hospital, Baltimore.  
Asst. Surg. Melvin H Pike, relieved at the marine hospital, New York and assigned to the marine hospital, Baltimore.  
Asst. Surg. W. P. Dearing, relieved at the marine hospital, Stapleton, N. Y. and assigned at the National Institute of Health, Washington, D. C.  
Passed Asst. Surg. Gordon A. Abbott, relieved at Baltimore and assigned at the marine hospital, New Orleans.

The following have been promoted and commissioned as passed assistant surgeons in the regular corps of the service:

Thurman H. Rose	Alfred B. Geyer
Victor H. Vogel	Roy E. Butler
Joseph G. Pasternack	R. C. Arnold
Robert H. Onstott	John L. Wilson
William G. Workman	George G. Van Dyke

#### The Registration of Foreign Physicians

The destruction of liberty of opinion in certain European countries and the persecution of scientists and physicians has produced an influx of refugees into this country, mainly from Germany. The medical refugees aroused some concern in the British Medical Association, which was expressed at the conference of overseas members, held during the Dublin meeting last July. It was said that any foreign national who was a graduate of medicine in his own country might after a short period of clinical study at a British school obtain registration in this country and practice in the colonies and dominions. The dominions committee of the association asked the council to consider the advisability of approaching the qualifying bodies with regard to the time required by those bodies for study in this country by foreign medical graduates prior to the qualifying examination and to urge that these should be required to undergo a minimum of three years' clinical study in Great Britain or Ireland before being admitted to the qualifying examination. At a recent meeting of the council of the association it was stated that the total number of foreign qualified physicians in this country going through the short course which entitled them to take the final examination of one examining body—the Conjoint Board of Scotland—was approximately 180. Of those who qualified, 150 were expected to remain in Great Britain and Ireland. An attempt would be made to place them judiciously, if they were Jews (which all of them were not) in cities where there was a large element of Jewish population. Of the remainder some might go to South America, but there was every reason to believe that none would go to Australia, New Zealand or South Africa. Therefore the problem was not that of safeguarding the dominions and colonies from persons qualified by reason of a short period of study but of dealing with the position of 150 persons at the most who would be settling in this country during the next eighteen months. The length of time one of the qualifying bodies allowed persons to study in this country before taking their final examination was the subject of consideration by a good many persons and conferences had taken place between the qualifying bodies. The council of the British Medical Association is definitely of the opinion that foreign medical graduates should be required to undergo a minimum of three years' clinical study in Great Britain or Ireland before they are admitted to a qualifying examination.

#### The British Graduate Medical School

The formation of the British Postgraduate Medical School to supply a long felt want, a medical school and hospital devoted to postgraduate teaching worthy of the metropolis of the empire has been described in previous letters. Appointments to the staff have now begun with three professorships. Dr F R Fraser has been appointed professor of medicine. He is at present university professor of medicine at St Bartholomew's Hospital. Graduating at Edinburgh in 1910 he was appointed assistant in medicine at the Hospital of the Rockefeller Institute, New York, in 1912 and assistant physician to the Presbyterian Hospital in 1914. In the war he was consulting physician to the Rhine army. In 1920 he became assistant director of the medical professional unit at St Bartholomew's Hospital and later in the same year director in succession to Sir Archibald Garrod. In 1925 he revisited the medical schools in the United States and Canada at the invitation of the Rockefeller Foundation. In 1927 he delivered the

Goulstonian lectures at the Royal College of Physicians on cardiac dyspnea. In 1928 he lectured in Australia on the invitation of the Melbourne Postgraduate Committee. In 1933 he again visited the United States as Abraham Flexner lecturer at Vanderbilt University. He has written principally on poliomyelitis, heart disease and exophthalmic goiter.

Dr James Young has been appointed professor of obstetrics and gynecology. He is obstetric physician to the Edinburgh Royal Maternity Hospital and gynecologist to the Edinburgh Royal Infirmary. Since 1920 he has been lecturer in clinical obstetrics and gynecology in the University of Edinburgh. He is the author of a well known textbook on gynecology and he has collaborated in the Combined Textbook of Obstetrics and Gynecology, which has emanated from the Scotch school. He has devoted special attention to maternal mortality and reported on the maternity services of Holland, Denmark and Sweden. He has investigated the toxemias of pregnancy and the histologic changes in the uterus during menstruation and pregnancy.

Dr E H Kettle has been appointed professor of pathology. He is university professor of pathology at St Bartholomew's Hospital. He was pathologist to the Cancer Hospital and assistant pathologist to St Mary's Hospital. His textbook on the pathology of tumors is well known. His published work has been on cancer and splenomegaly and he is now engaged in experimental researches on silicosis and other industrial diseases.

#### Research in Bacterial Chemistry

The Medical Research Council has made arrangements for combined chemical and bacteriologic investigation into the conditions that govern the life and multiplication of pathogenic microbes. These investigations have been made possible by cooperation of the Middlesex Hospital Medical School, the trustees of the late Lord Leverhulme and the Sir Halley Stewart Trust. Accommodation and facilities are being provided at the Middlesex Hospital in the Bland Sutton Institute of Pathology and the adjoining Courtauld Institution of Biochemistry. The investigation will be directed by Dr Paul Fildes, FRS, who has been appointed a member of the scientific staff of the Medical Research Council. The other workers are Dr G P Gladstone, Dr G M Richardson and Mr Knight. The arrangements took effect June 1 and the support given is sufficient for an initial period of five years.

#### The British Medical Association and the Use of Drugs by Midwives

The question of the use of drugs by midwives has been under the consideration of the British Medical Association for some time. In 1923 the council of the association represented to the Central Midwives Board that midwives should not be allowed to administer chloroform except under the supervision of a physician. The board agreed with this view. The association has also on many occasions protested to the Ministry of Health and to the Central Midwives Board against the assumption that a midwife should be allowed to administer drugs other than a simple aperient or ergot after delivery. Under the present regulations the midwife receives instruction in the use of drugs, but the association contends that she is thereby led to assume dangerous responsibilities for which there is no real need. In the short time at her disposal, her training on this subject must obviously be directed merely to the immediate effect of a few drugs on certain conditions. There can be no training on the remote and general action of drugs on the patient—a thing requiring the training of the medical curriculum. Drugs that need to be administered during the course of a confinement, such as opium, chloral and solution of pituitary are potentially dangerous. The association holds that conditions in which drugs of this nature seem to be needed are indications that a physician should be summoned.

The council of the association has informed the Ministry of Health and the Central Midwives Board that it views with apprehension the proposed extension of the freedom of the midwife to administer drugs on her own responsibility. The rule of the Central Midwives Board at present governing the use of drugs by midwives is as follows: "A midwife must not on her own responsibility use any drug unless in the course of her training she has been thoroughly instructed in its use and is familiar with its dosage and methods of administration or application. The board would regard the giving of pituitary extract before the birth of the placenta, except under a grave emergency, as treatment outside a midwife's province."

### The Toll of the Roads

During the week ended June 30, 140 people were killed and 5,000 injured on the roads of Great Britain. This brings the total for the first six months of the year to 3,224 killed and 101,694 injured. In other words, eighteen people have been killed and 600 injured every day. In the last eight and one-half years 54,138 persons have been killed and 1,522,704 injured. The figures for the first six months of this year are an increase on those of the previous year for the same period, and every year for some time has shown an increase on the previous one. The following table gives the figures for the last eight years:

Year	Killed	Injured	Total
1926	4,886	133,888	138,774
1927	5,329	148,575	153,904
1928	6,138	164,838	170,976
1929	6,696	170,917	177,613
1930	7,305	177,895	185,200
1931	6,691	202,119	208,810
1932	6,667	206,450	213,117
1933	7,202	216,328	223,530

### Memorial to Manson and Ross

The incorporation soon after the death of Sir Ronald Ross of the Ross Institute in the London School of Hygiene and Tropical Medicine was reported in a previous letter. The official ceremony took place at the school. The earl of Athlone, chancellor of the University of London, unveiled a memorial tablet to Sir Patrick Manson and a bust of Sir Ronald Ross. Lord Athlone said that Manson had the vision and courage to inspire teaching and research in tropical medicine. He was a pioneer in new paths of medicine. He left Scotland at 21, went to Formosa and worked there and in China for nearly a quarter of a century in isolation. He discovered that the mosquito acted as a host in the transmission of filaria. He also discovered several new diseases and parasites of man. On returning home he founded the London School of Tropical Medicine. Sir Ronald Ross was inspired by Manson, the father of tropical medicine, to investigate his theory that the mosquito carried the germs of malaria. His success led to the investigation of insects as carriers of disease.

### The Sterilization of Mental Defectives

It was stated previously, that a committee of experts appointed by the government to inquire into the sterilization of mental defectives reported unanimously in favor of voluntary sterilization. The matter next came before the Mental Hospitals Committee of the London County Council, which by a majority approved of this recommendation. This decision then came before the General Purposes Committee, which arrived at the conclusion that the facts in possession of the Council were not sufficient to warrant it in expressing an opinion. Finally the matter has just come before the whole council, when a discussion took place. In moving that the council support the unanimous opinion of the government committee, a member stated that it was a strong one. The voluntary aspect was emphasized and the treatment was hedged round by every safeguard. A growing percentage of mental defectives and

their high fecundity were pointed out. However, a labor member moved an amendment that "the knowledge of the facts do not warrant the council in expressing an opinion." This was carried by 63 votes to 44, a majority which corresponds to the predominance of the labor party on the council. The party did not officially oppose sterilization but allowed a free vote. But, on the whole, the labor party is against sterilization, as it regards mental deficiency, like other social evils, as due to "the capitalist system" and to be remedied by getting rid of that. The labor member who moved the amendment said that the inheritance of mental deficiency had not been proved and suggested that unsatisfactory environmental conditions were the cause, for which of course he held capitalism responsible.

### Urologists in High Favor, Faure an Exception

Prof. Jean-Louis Faure has been chosen a member of the Academy of Sciences, which is one of the five sections of the Institut de France. The Academy of Medicine, with its hundred members, created much later than the institute, does not form part of it. In the Academy of Sciences, in which one finds sections of mathematics, physics, chemistry and several others, the section of medicine and surgery has only six seats. Membership is much sought after, as a supreme distinction, by eminent physicians who already have been honored by the Academy of Medicine. The selection of members by a group consisting chiefly of mathematicians, physicists and the like who have little knowledge of medicine, is sometimes surprising. The public has often been malicious enough to remark that the institute, many of whose members are aged, showed a marked preference for specialists in urology, probably because they could use their services to care for their prostates and bladders. Also the three members who represent surgery in the "Institut" are nearly always urologists. Guyon and Bazy, for example, gained entrance without difficulty, although hardly representative of the science and art of surgery as a whole. An election was held three months ago in which Gosset, a comparatively young man, although he had performed many prostatectomies, was admitted on the first count, easily defeating Jean-Louis Faure and Hartmann. At the recent election Jean-Louis Faure was again a candidate, in competition with Hartmann and two young urologists, Marion and Chevassus. He won in the contest in spite of the fact that he is a gynecologist and hence unable to render any special service to the electing body. His success was therefore all the more meritorious. It is probable that the members have had their eyes opened to the fact that their traditional preference for urologists is a cause of many smiles. Jean-Louis Faure is, moreover, an eminent surgeon, aged 70, who succeeded Pozzi in 1919 in the chair of clinical gynecology at the Faculté médicale de Paris. His publications are numerous and his lectures at the Hôpital Broca are highly appreciated. He has often represented France in foreign countries (particularly in America) at congresses and on scientific missions. He possesses a high literary culture and has published a book, "L'Âme du chirurgien," whose perfection of style and loftiness of thought would seem to mark him as a successful candidate for membership in another section of the "Institut", namely, the French Academy.

### The Disposal of Garbage

The problem of disposing of garbage from households has been solved differently in different countries. In Paris, where the garbage amounts to thousands of tons a day, household garbage is placed in metal receptacles at the curb, these being provided with tight fitting covers to keep out the rats. Before

dawn these collections of garbage are transferred to huge autotrucks and transported to crematories outside the city. The garbage is passed over screens in order to retrieve materials that are still usable. The remainder is burned in incinerators at a high temperature, which leaves only the mineral elements, and these are immediately transformed into bricks, which are sold as excellent construction material, which pays in part the great expense of this important sanitary service. At Aix-en-Provence another system has been adopted, which, by utilizing a process of spontaneous fermentation, secures a residue that does not need to be sterilized by high temperature but can be used in a different form. The household garbage of the city is transported to an establishment, where it is divided into several classes by means of interesting machines and is then transferred to large compartments, in which the material is allowed to ferment for twenty-one days, after which it is stored in its new form in a large warehouse and left for another month. It is later reduced by mechanical processes to a black powder resembling humus and termed "zymos." During the course of fermentation in the large compartments, the temperature reaches 80 C (176 F), which destroys absolutely the ova of parasites and all saprophytic or pathogenic organisms. Professor Carrieu and Dr. Papas emphasized that a general use of this method would do away with the accumulations of malodorous substances in areas just outside the city.

### Is a Federal Cancer Law Needed?

For some time there has been discussion, in this era of advanced health protection legislation in Germany, as to whether a law pertaining to cancerous disease should be enacted. The Düsseldorf dermatologist Prof. Thomas Schreus is taking special interest in the subject. The essential feature of his endeavors is to prepare the way for a publicity crusade by providing for free examination of all cancer suspects. It is evident, he says, that such free examination must form a basis of all cancer control. For no matter what remedy is employed after the disease is diagnosed and irrespective of the potency of remedies that may be discovered, the prompt recognition and the early treatment of all cancerous persons must constitute the basis of all organized combating of cancer. Schreus takes a broader view of the situation than other authors (Professor Lönne, for example), who have confined their suggestions to the gynecologic aspects of the problem. Schreus recommends that the following features be added: 1. Issuance of a general warning, often repeated, to the whole population to submit to examination. 2. Assurance of the examination by an annually renewable gratuitous examination permit, given out by the Krankenkasse or by the public authorities, for this would be scarcely feasible without legislative enactment. 3. Establishment of a fixed form of examination. In order to preserve all records in a systematic manner every German on attaining age 40, should be provided with a record book, which should contain information on cancer, and a copy of the cancer protection law, and, finally, the questionnaire on hereditary and familial conditions. After the death of the holder these health record books should be turned over to the federal bureau of health. In the presence of cancer or suspected cancer, compulsory notification should be required. Care should be taken to provide physicians and medical students with adequate instructions. 4. Assurance of the necessary treatment for all persons affected—that is a notification system with centrals at various bureaus.

Schreus scouted the idea that the distribution of health record books might awaken among the population a chronic

fear of cancer and ventured that cancer and the fear of cancer together are not so bad as ignorance of cancer. For normal persons with a keen zest for life, who demand protection in this field as in all others, the health record book would be the talisman that would procure for them quiet sleep. It is not known that such legislative measures are being considered, but experts are emphasizing that predisposition to cancer is a concrete factor that must be reckoned with, and which today (for example, in the matter of advice to candidates for marriage) plays already a significant role.

### Unrecognized Tuberculosis in the Storm Troops

Dr. Kattentidt pointed out before the Münchner Aerztlicher Verein recently that among the national socialist storm troops and in the work camps there are many persons with open tuberculosis, although they are ignorant of the fact. These cases must be taken seriously, because the population of the work camps mingle closely, and the rural population is much more sensitive. Unrecognized tuberculosis is destructive because it has time to extend itself uncontrolled. Grave tuberculous processes may be found in persons who distinguish themselves in sport. There is a well known football player with tuberculous cavities, and a young woman who has made a record as a swimmer in spite of the fact that she is tuberculous. Exceedingly grave processes do not necessarily present manifestations that attract the attention of the bearer. About three fourths of the unrecognized cases of tuberculosis cannot be diagnosed either by percussion or by auscultation but only roentgenologically. The number of unrecognized cases of tuberculosis increases with every older age group. In Munich 27,000 students have been examined fluoroscopically in recent years. In every 200 students a case of open tuberculosis was found, in every fifty students extensive but healed scar tissue was observed, and in every fifteen students a small scar was noted. It is difficult to decide how best to combat the disease. The first measure should be a thorough chest examination for every person. Roentgen examination is especially important for physicians working among the storm troops and among athletes. No physician should say that a person is healthy until he has subjected him to a fluoroscopic examination. The systematic examination of the sputum is not always feasible, because few people seem to know that they have an expectoration. The danger of infection among the storm troops and in the work camps is greater than in the families. There will be many claims for damages against the state if the examinations made when candidates entered the work camps were not carefully done and did not exclude the unfit. A "light" work service is a misnomer, and only healthy persons should be enrolled. Urinalyses are likewise necessary, for in 1,500 examinations of urine fifteen serious urinary observations were made, for example, a renal tuberculosis, although the examinee did not feel ill. The serial examinations are cheap. In a day as many as 150 persons can be examined with the fluoroscope. Interpretation of the lights and shadows should be made by a physician with special training. The actual cost of such examination is about 20 cents per person. The method is not practicable if hospitals charge from 15 to 20 marks (\$5.70 to \$7.60, current). In all Germany there are probably 350,000 open cases of tuberculosis, which are susceptible of improvement or cure whereas in the sanatoriums there are only 30,000 beds, many of which are vacant.

### The Electrical Potential of the Skin in Relation to Colds

Professor Munk addressed recently the Berlin Medizinische Gesellschaft. In winter and in the transitional periods, disorders occur that, without discrimination, are grouped under the head of 'colds.' There is scarcely a medical school that has not advanced a theory concerning colds. Munk has reported

the outcome of experiments that clarify a previously unknown function of the skin. If one places an electrode at each of two points on the skin (for example, the forehead and the palm of the hand), he will observe a difference of potential that is measurable with the galvanoscope and remains constant during the lifetime of the person. Between two symmetrical points of the body there is no difference of potential.

Similar processes in plant physiology have long since been known. The system has a high degree of stability. Thus, in a multiple sclerosis patient in whom malaria treatment was tried, the potential difference remained the same during an increase of temperature from 37.1 C to 40.1 C. If one checks the secretion of the sweat glands with atropine, or if one induces perspiration with acetylsalicylic acid, the potential difference does not change. These constants may be demonstrated also in the frog and in the guinea pig. The constancy is, however, interrupted if one endeavors, as did Munk, to reproduce the process of taking cold by removal of the shoes, placing the feet in hot or cold water, or by exposure to draft of air. The act of sneezing is conceived of by Munk not only as due to removal of an unpleasant tickling sensation but also as a first reaction and warning. Through the act of sneezing the disturbed equilibrium of the electromotor force is restored. It is not known whether temperature stimuli or other currents produce these changes in the electromotor force. In any event, through the process of taking cold the system of electromotor force as a function of the skin is markedly disturbed—more than the heat regulatory apparatus.

Munk has conceived the possibility that, just as bacteria require a certain optimum, the undisturbed electromotor force of the skin constitutes a certain protective apparatus that makes the invasion and action of bacteria impossible.

### The Social Services and the Hospitals

At the third Congress international des hopitaux, Dr Daels of Ghent emphasized the importance of an understanding between the hospital and the medical social services and the public. The hospital must not assume a monopolizing attitude. It should recognize that certain diseases may be better treated at home than in the hospital. A clinical service is not complete if it is not aided by a visiting nurse who is familiar with the home and the financial situation of the family. It is desirable that the ward nurse give to the visiting nurse the most necessary information in the case in which urgent aid is needed. The hospital should not allow patients to be interrogated by several persons with regard to their financial situation. It is highly desirable that the ward nurse shall gain the confidence of persons whom she is to serve. Thus she will obtain from patients the necessary information more easily than a visiting nurse.

The private organizations giving medical and social aid are excellent, but they are, at the most, of secondary importance, for it is absolutely necessary that continuity of the aid be assured and that precise methods be employed in the investigations and the rendering of medical social aid.

### The Antivenereal Crusade in the Hospitals

The third Congress international des hopitaux passed a series of resolutions that may have a significant result in the antivenereal crusade.

1 From a medical and social point of view, patients affected with syphilis and gonorrhea should be admitted to all general hospitals that have a qualified technical personnel. No moral distinction should be made between venereal patients and other patients, even though the former are treated at public expense.

2 The l'Union internationale contre le peril venerien should be asked to study and report on the question as to what measures can be taken to bring about a closer union between the practicing physician and the hospital services concerning scientific progress in the diagnosis and treatment of syphilis and gonorrhea.

3 Because a large number of patients with syphilis and gonorrhea enter the hospitals in the services of internal medicine, gynecology, obstetrics and the like, and because the relations between syphilis and gonorrhea, and the acute diseases are often obscure, it is earnestly recommended that the custom be encouraged of asking the specialist in venereal diseases to participate in the examination of all obscure cases.

4 It should be emphasized and the prophylaxis of congenital syphilis should become universal in the hospitals through an active collaboration between the syphilologic service and the obstetric service.

## The Red Cross in Luxemburg

The Red Cross in the Grand Duchy of Luxemburg has developed its program of action in a remarkable manner. It conducts each year an extensive publicity campaign and drive for members, and every week talks on hygienic subjects are broadcast under its auspices. Its visiting nurses go to adjacent foreign countries for graduate work in their profession. It has organized a prenatal consulting service and a dispensary of mental hygiene at Luxemburg, a day nursery at Esch sur Alzette, and at Redange a center for placement in families.

The detection of cancer cases is taken over by the Red Cross and arrangements for their treatment have been provided at Strasbourg. Active collaboration exists between the Red Cross of Luxemburg, on the one hand, and the Ligue antituberculeuse, the Ligue antialcoolique, the Association des camps detes and the Societe d'hygiene populaire et scolaire. It provides aid for persons in distress—particularly for German refugees. The Red Cross has begun the construction near Luxemburg of a maternity, with a home for mothers and a school for the training of midwives.

## BUCHAREST

### The Death of Professor Cantacuzino

The death of Prof. Jean Cantacuzino of Bucharest University, a renowned bacteriologist, has been announced. A descendant of the once ruling Cantacuzino family, he attended the secondary schools in Paris, where later he acquired the title of doctor of philosophy in the natural sciences. In 1894 he became a doctor of medicine. From 1894 to 1896 he was professor of animal morphology at the philosophical faculty of the University of Jassy, Rumania. On the invitation of Professor Metchnikoff he went to the Pasteur Institute in Paris in 1896 and there carried on research until 1902, when he was offered the position of vice director. He did not accept this position because in Bucharest the chair of experimental pathology had become vacant and he was invited to accept it. He remained in this position until he died.

In 1905, together with Professor Athanasiu, he founded the Rumanian Biological Society and in the same year launched the *Revista stiintelor medicale*, which is regarded as the foremost medical journal in Rumania. In 1908 he was appointed director of the board of public health. In 1913 he acted as chief epidemiologist in the Bulgarian war. In 1920 he founded the serum and vaccine institute named after him and in 1928 launched another periodical, the *Archives mensuelles roumaines de pathologie experimentale*, appearing in French. He brought to life the Rumanian Society for the Prophylaxis of Tuberculosis. In 1931 he was minister of public health. His favorite

study was the mechanism of immunity. His book on the role of phagocytosis in the struggle of the organism against the cholera vibrio aroused wide interest.

Professor Cantacuzino was the first to transmit scarlet fever infection to laboratory animals, which he did in 1911. He was a zealous advocate of the Calmette vaccination. Up to 1932, half a million babies received the BCG vaccine, 350,000 of these were in France, 70,000 in Rumania and 80,000 in the rest of the world. His serum and vaccine institute is conducted in the most exemplary manner and under the most scientific supervision. In this institute, three university professors and thirty physicians are employed. Cantacuzino's hobby was music and art. He owned one of the greatest art collections in Europe. His simple views were reflected in his will, in which he requested an unpretentious funeral.

#### A New Medical Monthly

*Sibul medical* is the name of a new medical monthly published in Sibiu, Transylvania. The editorial committee consists of Drs. Capitanovici, Filipescu, Preda and Stoichita. The paper is going to deal with scientific problems, but its chief topics will be social hygiene and propaganda for a more effective public health service. The paper is independent and is not subordinated to any magistrate or association. The first issue appeared on the first of June. The price of subscription is only 100 lei (one dollar) a year.

#### The Military Service of Physicians

Up to now the Rumanian military system has favored physicians who have not had to undergo military drill. They have been obliged to serve only after having graduated and then only in military hospitals for four weeks with the salary and rank of a lieutenant. Now the service will be extended to one year, the four weeks being insufficient to learn military medical practice.

#### The First Psychoanalytic Society in Rumania

Under the name *Societate Romană de Cercetări Psihologice* a scientific association was founded last month for the purpose of furthering psychoanalytic science in Rumania. Professor Radulescu Motru has been elected president of the association, which already has forty-five members. It is going to meet monthly.

#### The University of Cluj

The University of Cluj made public data for the 1933-1934 school year showing that 4,469 students enrolled an increase of 345 over the previous year. Of these 984 were medical and 387 pharmaceutical students. 2,722 were Rumanians (60 per cent), 922 Magyars (20 per cent), 447 Jews (10 per cent), 445 from Saxons (7 per cent), 112 Russians (2 per cent), 2 French and 6 Czechoslovakians. The budget of the university for the year amounted to 65,307,180 lei (about \$653,071).

#### The New Polish Registration Law

Rumania is an immediate neighbor of Poland. Their common frontier is only a few hundred miles. In southern Poland, near the Rumanian frontier there is no university but there is one nearby in Czernowitz in Rumania. Some Polish students study in Czernowitz. According to the new law the number of foreign diplomas has been restricted to 10 per cent of the number of diplomas issued within the country. Since in Poland about 300 physicians get a diploma annually, only thirty foreign diplomas will be recognized. Foreign applicants for recognition have to attend three terms and pass all examinations at a Polish university. The new law also prescribes that those who have graduated abroad may file petition for recognition only after the lapse of ten years and those who will graduate in 1936 after the lapse of twenty years. This stringent measure was made on the instigation of the medical chambers to

limit overproduction of physicians. According to authoritative statistics the ratio of physicians to population in Wolhynia and Little Poland is 1:6,000. A committee has been formed in Paris to protest against the Polish law and to do everything possible for its repeal or at least mitigation of its provisions.

#### Europeans in the Dutch East Indies

Dr. C. W. F. Winckel has published a study on the European population of the Dutch East Indies. During the eighteenth and nineteenth centuries, the mortality was high. It was not easy to collect statistics, for only in recent years has a bureau of statistics been organized. In 1920, 91.7 per cent of the Europeans in the Dutch East Indies were Netherlands, 4.7 per cent were Americans and Australians, 2.5 per cent were Japanese, 0.3 per cent were Chinese and 0.8 per cent belonged to groups of Europeans of the second generation. Since Jan. 1, 1934, it has no longer been the department of justice that has charge of the collection of statistics on Europeans but the Central Bureau of Statistics. The same is true with regard to the collection of statistics on the causes of deaths. These are first reported to the local health officer, who forwards them to the central bureau.

#### STUDY OF THE SITUATION ACCORDING TO THE DIFFERENT AGE GROUPS

There are more European men than women in the East Indies. Not until one approaches age 70 does one find more women than men. The majority of the European population belongs to the 20-56 age group. The number of children increases with the group of school age, which is explained by the system of adoption and legislation. The number of aged persons is small because many persons return to their native country at the end of their career.

#### BIRTHS

The number of births is difficult to establish because of the large number of emigrants who return to their native country with their children after completing their sojourn in the Indies, and because of the large number of illegitimate children who are recognized and legitimized. Over a period of three years there were 22,374 births, which represents a birth rate of 31.18 per thousand of population. In 1926 the infant mortality was 65.4 per thousand, and in 1929-1931 it was 69.2 per thousand.

#### CAUSES OF DEATH

Among the chief causes of death may be mentioned typhoid, malaria and dysentery. Measles is less grave than in the Netherlands. Tuberculosis is chiefly of the pulmonary type. Malignant tumors are rare. Biliary cirrhosis is frequent. Many persons die from an unknown cause, since not every one calls in a physician during his last illness.

#### Classification of Causes of Death

	Number of Deaths per 10,000 of Population
1 Typhoid	186
2 Malaria	181
3 Dysentery	119
4 Pulmonary tuberculosis	540
5 Apoplexy	309
6 Cirrhosis of liver	41
7 Smallpox	4
8 Pneumonia	362
9 Unknown causes	1101

It appears that (1) the mortality rate of Europeans in the Dutch East Indies is one and one-half times that of the Netherlands, (2) the high mortality is due to certain acute diseases (malaria and abdominal infections), otherwise the mortality would be no higher than that of the Netherlands, compared

with the past, when the colonies were in an alarming state, the present mortality rate may be regarded as ideal, although the organization of public health still leaves much to be desired (the improvement dates more particularly from the last two decades, which is not surprising when it is recalled that hygiene in general, and tropical pathology in particular, are just beginning to bear fruit), and (4) mortality is not the only basis for an estimate of the state of health of a people, but it is an important factor

#### Malaria in the Rhine Delta

At a meeting of the health section of the League of Nations, Mr Swellengrebel discussed malaria in the Rhine delta in the Netherlands. If the Rhine delta has become a malarial region, it is because it has been utilized for a purpose for which nature did not intend it. The formation of tracts of low land has brought about the creation of hiding places for the larvae of *Anopheles*. The systematic retrieving of land areas has its dark and its bright side. Such areas are more or less unhealthful but present nevertheless certain sanitary advantages. These advantages have accrued not to the retrieved area but to the hinterland. Each new tract has served to protect its hinterland against encroachments of the sea. Likewise, the surface waters of the hinterland have lost their salinity, and *Anopheles maculipennis* has been able to establish itself here. Consequently new areas must be recovered in order to protect the old areas, that is to say, one creates constantly new lurking places by suppressing those that existed previously. The recovery of lands, which is going on at the present time in the region of the Zuider Zee, represents an effort to remedy this evil by eliminating the malaria of the hinterland without the new areas becoming malarial. This method has for its basic purpose the creation, in the center of four "polders," of an immense reservoir protected from the sea by a dike extending from the province of North Holland to that of Friesland. If this experiment succeeds, the province of North Holland, at present the principal focus of malaria in the Netherlands, will be the first to get rid of its brackish waters and of its fauna of *Anopheles maculipennis*, var *atroparvus*.

#### Institute for Research on Heredity

A Netherlands institute for research on the characters of heredity in man and the biology of the races was recently created. It is divided into three sections: (1) biogenealogy, (2) medical statistics on the examination of hereditary characters, and (3) anthropologic study on the biology of the races.

#### BUENOS AIRES

(From Our Regular Correspondent)

June 1, 1934

#### Recording the Cardiac Sounds

Orias and Braun Menendez made graphic records of the cardiac sounds in 100 medical students from 19 to 23 years of age by the method of Wiggers and Dean. Only the first and second sounds were present in thirty-four, the third sound was clearly recorded during the final instants of diastole in thirty-two, an auricular sound, besides the two normal sounds, was recorded in three, four sounds, the auricular and the first, second and third sounds, were perfectly recorded in nine. The recording of the phonocardiogram, simultaneously with the venous pulse, is a great advantage. They analyzed, by means of the simultaneous recording of the phonocardiogram and the venous pulse, the cardiac sounds of twenty patients with gallop rhythm who had clinically improved. In about half of the cases the extra sound occurred at the final moment of diastole simultaneously with the final portion of the descending line of the V wave of the phlebogram. In one fourth of the cases the extra sound occurred at the moment of the auricular

contraction, simultaneously with the a wave of the phlebogram. The moment of production of the gallop rhythm has been determined by the simultaneous registration of this rhythm with the electrocardiogram. However, by this method one is liable to interpret as presystolic murmurs those which the phlebogram proves to be related to the diastole.

#### Phrenicectomy

Phrenicectomy is frequently resorted to in the treatment of pulmonary tuberculosis. Drs Finochietto and Vaccarezza have developed a technic using incisions only 8 to 10 mm long. They have performed the operation in nearly 300 cases without hospitalizing the patient. The operation is not difficult if special instruments are used and the technic is carefully followed. The scar is insignificant.

#### Hospital Physicians

The law providing for promotion for physicians in the hospitals was received with great enthusiasm in spite of some of its queer sections. For instance, each physician must either present some work during the year or publish two medical articles a year. But when the time for enforcing this comes, there are many exceptions, and several new appointments have been made without fulfilling the regulations. This fact has brought about criticism and uneasiness among the physicians of the hospitals.

#### University News

Dr F. Lejarza has been appointed head of the University of Litoral.

Dr Puñero Garcia was appointed director of the School of Medicine but he resigned, Dr C. Alvarez was then given the appointment.

The appointments made by Dr Izzo in 1928 were annulled and the chairs occupied by Drs Abalos, Rueda, Coulon, Vignolles and some others are now vacant.

A contest has been opened in the University of Cordoba to appoint a director of the institute and a professor of physiology. Drs O. Orias, D. Bariları and A. Sartori are candidates under consideration.

The Academia Nacional de Medicina of Buenos Aires has appointed Drs Romagosa of Cordoba and E. Finochietto, P. Chutro and A. Zabala of Buenos Aires honorary academicians.

#### Deaths

Dr Angel Gallardo, rector of the University of Buenos Aires, member of the Academy of Medicine of Buenos Aires, minister of foreign affairs and formerly representative of Argentina to several countries, aged 67, died, May 13.

Dr Jose Lignieres, member of the Academy of Medicine of Buenos Aires, a French bacteriologist, pupil of Nocard, recently died. He was opposed to the general vaccination of children with B. C. G. vaccine. He believed that only children from tuberculous parents should be vaccinated with this vaccine.

Dr Carlos Heuser, a well known radiologist, died, aged 56.

#### Marriages

WALTER SWAN BURRAGE, Brookline, Mass., to Miss Katherine Sanford Riley of Worcester, June 22.

CHARLES EDGAR BALLARD, Belmont, N. C., to Miss Marie Almeda Wyatt of Easley, S. C., in June.

WILLIAM BERMAN to Miss Ruth Jonette Einson, both of Yonkers, N. Y., June 15.

JOHN JAMES DELANY, Galveston, Texas, to Miss Jennifer Jaynes, Temple, June 3.

HARRY LOUIS BERMAN to Miss Ella Stein, both of Chicago, June 24.

Deaths

Theodore H Weisenburg  $\oplus$  Philadelphia, professor of neurology at the University of Pennsylvania Graduate School of Medicine since 1907, and editor in chief of the *Archives of Neurology and Psychiatry* from its foundation in 1919, died suddenly, August 3, of carcinoma of the liver, aged 58. Dr Weisenburg, a native of New York, was graduated in medicine from the University of Pennsylvania School of Medicine in 1899. In 1901 he went to the Philippine Islands as assistant surgeon in the United States Army, where he served for two years, returning to begin practice in Philadelphia in 1903. He was appointed instructor in neurology and neuropathology at his alma mater in 1904 and became professor of neurology in the graduate school in 1907. Dr Weisenburg held various offices in organizations concerned with his specialty. He served as secretary of the Section on Nervous and Mental Diseases of the American Medical Association for two years 1905-1907, and in the latter year was made chairman. In 1917 he was president of the American Neurological Association and at the Association for Research in Nervous and Mental Diseases. He was also a member of the American Psychiatric Association. During the World War Dr Weisenburg served in the Army Medical Corps. His hospital affiliations included the Philadelphia Orthopedic Hospital and Infirmary for Nervous Diseases, Graduate Hospital of the University of Pennsylvania, Wills Hospital and Philadelphia General Hospital. In addition to his editorial activities, Dr Weisenburg contributed to scientific journals many articles on nervous and mental diseases.

Henry Anthon Lewis Ryfkogel  $\oplus$  San Francisco, University of California Medical Department, San Francisco, 1894, fellow of the American College of Surgeons, clinical professor of surgery, Stanford University School of Medicine, past president of the California Medical Association, formerly member of the state board of medical examiners, medical superintendent of the San Francisco Polyclinic, for many years visiting surgeon to the San Francisco Hospital, aged 60, died, June 11, of heart disease.

James Vance Ferguson  $\oplus$  El Dorado Ark., Tulane University of Louisiana School of Medicine New Orleans, 1923, fellow of the American College of Surgeons, past president of the Union County Medical Society, Henry C Rosamond Hospital, aged 33, died, July 8, at the Mayo Clinic, Rochester, Minn., of perforation of an ulcer of the stomach on the staff of the hospital, of complications following.

George Benjamin Collier  $\oplus$  New Orleans, Tulane University of Louisiana School of Medicine New Orleans, 1915, member of the American Academy of Ophthalmology and Otolaryngology, fellow of the American College of Surgeons, on the staffs of the Southern Baptist Hospital and the Eye Ear Nose and Throat Hospital, aged 44, died July 9, of acute gastro-enteritis and acute nephritis.

Jacob H Heimark, Moorhead, Minn., Minneapolis College of Physicians and Surgeons medical department of Hamline University, 1903, member of the Minnesota State Medical Association, at one time secretary of the Clay-Becker Medical Society, formerly health officer of Moorhead, on the staff of St Ansgar Hospital, aged 57, died June 25, in Minneapolis, of heart disease.

Frank William Romaine  $\oplus$  Major, M C, U S Army, Spokane, Wash., Georgetown University School of Medicine, Washington D C, 1905, fellow of the American College of Surgeons, served during the World War entered the medical corps of the regular army as a captain in 1920 and in 1929 made a major, aged 56, died May 7, of heart disease.

Joseph Mayer Rice Philadelphia College of Physicians and Surgeons, Medical Department of Columbia College New

THEODORE H WEISENBURG, M.D.,  
1876-1934

York, 1881, editor of the *Forum*, 1897-1907, author of "The Public School System of the United States", and "Scientific Management in Education", aged 77, died, June 24, in the Jefferson Hospital, of heart disease.

Peter Taylor Grant  $\oplus$  Grand Rapids, Mich., University of Louisville (Ky) School of Medicine, 1909, member of the American Academy of Ophthalmology and Oto-Laryngology, served during the World War, aged 50, on the staff of St Mary's Hospital, where he died, July 16, of streptococcal infection.

Taylor Hurst, Hazard, Ky, University of Louisville School of Medicine, 1909, member of the Kentucky State Medical Association, member of the board of education, part owner of the Hurst-Snyder Hospital, aged 54, died, July 5, in St Joseph's Hospital, Lexington, of carcinoma of the transverse colon.

Daniel Laurence Healy, Framingham, Mass., Harvard University Medical School, Boston, 1898, member of the Massachusetts Medical Society, formerly member of the school committee, on the staffs of the Framingham Union and Natick hospitals, aged 62, died, June 22, of chronic myocarditis.

William Newbold Watson  $\oplus$  Philadelphia, Medico-Chirurgical College of Philadelphia, 1892, aged 69, at various times on the staffs of the Children's Hospital, Methodist Episcopal Hospital and the Joseph Price Memorial Hospital, where he died, July 1, of carcinoma of the colon.

Solomon Horwitt, New York, Cornell University Medical College, New York, 1907, member of the Medical Society of the State of New York, on the staffs of the Bronx Maternity and Mount Sinai hospitals and the Vanderbilt Clinic, aged 55, died, July 1, of cancer of the stomach.

Edwin Sylvester Cornwell  $\oplus$  La Salle, Mich., University of Louisville (Ky) School of Medicine, 1897, past president of the Monroe County Medical Society, aged 67, on the staff of the Monroe (Mich) Hospital, where he died, June 30, of interstitial nephritis and myocarditis.

Eugene P Ellenson  $\oplus$  Chippewa Falls, Wis., Rush Medical College, Chicago, 1892, past president of the Chippewa County Medical Society for three years, health officer of Chippewa Falls, on the staff of St Joseph's Hospital, aged 65, died, June 17, of heart disease.

Herbert Miller Robertson, Santa Ana, Calif., Southern Homeopathic Medical College, Baltimore, 1897, member of the California Medical Association, for many years member of the state board of medical examiners, aged 61, died, June 1, of carcinoma of the stomach.

Hallward J Thornby, Moorhead, Minn., Minneapolis College of Physicians and Surgeons, Medical Department of Hamline University, 1909, member of the Minnesota State Medical Association, on the staff of St Ansgar Hospital, aged 52, died June 17.

Wilford J Austin, Spokane, Wash., University of Minnesota Medical School, Minneapolis, 1905, member of the Washington State Medical Association, aged 59, died suddenly, June 19, of diabetes adenoma of the prostate perirectal abscess and pulmonary embolism.

George Hillard Hill  $\oplus$  Worcester, Mass., Harvard University Medical School Boston, 1894, fellow of the American College of Surgeons, formerly on the staffs of the Memorial and Worcester City hospitals, aged 65, died, May 18, of pneumonia.

Robert Abraham Douglas, Tulsa, Okla., Starling Medical College Columbus, 1892, member of the Oklahoma State Medical Association, served during the World War, aged 67, died June 16, in the A C H Hospital, Shawnee, of angina pectoris.

Joseph Herman Karsch, Memphis Tenn., Vanderbilt University School of Medicine, Nashville, 1896, member of the Tennessee State Medical Association, aged 59, died suddenly, June 14, while in Baltimore, of cardiovascular renal disease.

**Samuel S Kittrell**, Louisville, Tenn, Chattanooga Medical College, 1894, member of the Tennessee State Medical Association, aged 66, died, June 6, in the Riverside-Fort Sanders Hospital, Knoxville, of otitis media and streptococci septicemia

**Robert Lee Wilkins**, Alexandria, Va, University of Virginia Department of Medicine, Charlottesville, 1901, member of the Medical Society of Virginia, aged 68, on the staff of the Alexandria Hospital, where he died, June 10, of septicemia

**James Sterling Dimmitt** ♂ Sherman, Texas, University of Texas School of Medicine, Galveston, 1921, fellow of the American College of Surgeons, on the staff of the Wilson N Jones Hospital, aged 43, died, June 26, of Hodgkin's disease

**Harry Whipple Johnson**, Bangor Maine College of Physicians and Surgeons, Baltimore 1908 member of the Maine Medical Association, aged 54, died, April 16, of septicemia, acute nephritis and empyema of the gallbladder

**William G Shaw** ♂ Wagram, N C, College of Physicians and Surgeons, Baltimore, 1892 past president of the Scotland County Medical Society, for many years member of the county board of education, aged 66, died, June 11

**Gustaf Adolph Persson**, Mount Clemens, Mich, Illinois Medical College, Chicago, 1898, member of the Michigan State Medical Society, aged 58, died May 19 in the Harper Hospital, Detroit, of pneumonia, following an operation

**John Allen Hamer**, Chlo S C, Medical College of the State of South Carolina, Charleston, 1904 member of the South Carolina Medical Association aged 54 died, July 11 in a hospital at Charleston, of chronic nephritis

**Aram Garahed Hejmanian** ♂ Anamosa, Iowa Rush Medical College Chicago 1893, fellow of the American College of Surgeons, bank president, on the staff of the Mercy Hospital, aged 71, died July 5 of coronary thrombosis

**William David Dorminy**, Fitzgerald, Ga, Atlanta College of Physicians and Surgeons, 1900 member of the Medical Association of Georgia, for many years president of the board of education, aged 63, died, June 4

**Isaac Errett Wolfe** ♂ Coeburn, Va University of Louisville (Ky) School of Medicine 1909 served during the World War aged 58, died June 20, in St Elizabeth's Hospital, Richmond, of carcinoma of the sigmoid

**Allen Jasper Harter**, Allendale, S C, Medical College of the State of South Carolina Charleston, 1887, member of the South Carolina Medical Association, aged 69, died June 27, of carcinoma of the throat

**Dan German Jr**, Franklin Tenn, Vanderbilt University School of Medicine, Nashville, 1931 member of the Tennessee State Medical Association, aged 26, was instantly killed, July 1, in an automobile accident

**Eugene Walters**, Winnipeg, Manit, Canada University of Minnesota Medical School Minneapolis 1895 Manitoba Medical College, Winnipeg, 1907, on the staff of the Victoria Hospital, aged 69, died, May 9

**Albee Amos Skeels**, St Albans Vt McGill University Faculty of Medicine Montreal, Que Canada 1897, served during the World War, aged 61, died, June 20, of diabetes mellitus and myocarditis

**Daniel Robert Lee**, Arcadia, Neb, State University of Iowa College of Medicine, Iowa City, 1890 aged 77, died suddenly, June 18, in Fort Collins, Colo, of angina pectoris and bronchopneumonia

**William H Pounds**, Paulsboro, N J, Hahnemann Medical College and Hospital of Philadelphia, 1886, formerly mayor of Paulsboro, aged 84, died, June 2, of cardiac decompensation and chronic nephritis

**Robert Coleman Rudy**, Detroit University of Michigan Homeopathic Medical School, Ann Arbor, 1886, aged 71, died June 13, in the Grace Hospital, of cerebral hemorrhage and arteriosclerosis

**William H Kinnicuttt**, Cleveland, Cleveland College of Physicians and Surgeons, Medical Department of Ohio Wesleyan University, 1898, aged 69, died, June 21, of lobar pneumonia

**Thomas Henry O'Toole** ♂ Norwood, Mass Jefferson Medical College of Philadelphia, 1897 aged 58 on the staff of the Norwood Hospital, where he died, April 4, of intestinal obstruction

**Miles Dawson Kelly**, Lonoke, Ark, University of Arkansas School of Medicine, Little Rock, 1913 aged 54, died, June 11, of uremia, carcinoma of the stomach and chronic nephritis

**Andrew Beattie Eadie**, Hemet, Calif, Trinity Medical College, Toronto, Ont Canada, 1886 Bellevue Hospital Medi-

cal College, New York, 1886, aged 74, died, May 29, of angina pectoris

**Rolando Kuehn**, Philadelphia Jefferson Medical College of Philadelphia, 1883, aged 74, died, May 11, in the Philadelphia General Hospital, of arteriosclerosis and heart disease

**Charles A Thompson**, Raymond, Ohio, Starling Medical College, Columbus, 1887 member of the Ohio State Medical Association, aged 72, died, June 6, of cerebral hemorrhage

**Albert Victor Widman**, Newark, N J, College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1887, aged 73, died, June 1, of cardiorenal disease

**William Shidaker Wire**, Norwood, Ohio, University of Cincinnati College of Medicine, 1930, aged 30, died, June 2, in the Good Samaritan Hospital, Cincinnati, of heart disease

**John Conant Stewart**, York Village, Maine Dartmouth Medical School, Hanover, N H, 1877, also a lawyer, aged 84 died, June 4, in the York Hospital, of coronary thrombosis

**Ezra Oscar Price**, Ladoga, Ind Kentucky School of Medicine, Louisville, 1889, aged 68, died, July 3, in a sanatorium at Martinsville, of cerebral hemorrhage and arteriosclerosis

**Lawrence George Geraghty**, Jersey City, N J, Georgetown University School of Medicine, Washington D C, 1937 aged 29 was killed, May 17, in an automobile accident

**Alexander Roth Robertson**, Pass Christian, Miss, Tulane University of Louisiana Medical Department, New Orleans 1895, aged 66, died, April 28, of cerebral hemorrhage

**Isaac Calvin Hollinger**, Boonville, Ind, College of Physicians and Surgeons, Baltimore, 1882, served during the World War, aged 79 died, June 14, of cerebral hemorrhage

**Robert J Woods** ♂ Smithville, Mo, Central Medical College of St Joseph 1898 aged 60, died May 4, in the Grandview Sanitarium, Kansas City, Kan, of heart disease

**Ernest Frederick Robinson**, Newton, Mass, University of Buffalo School of Medicine, 1891 aged 64 died, June 6, of agranulocytic angina, septicemia and pneumonia

**Francis William Hartley-Hellyer**, Baltimore (licensed in Maryland in 1894), aged 76 died, May 23, in the University Hospital, of hypertensive cardiovascular disease

**Elon Howard Nelson**, Mount Healthy, Ohio, Miami Medical College Cincinnati 1903, member of the board of education, aged 58, died, May 13, of heart disease

**Benjamin C Harris**, Lobata, W Va, Kentucky University Medical Department, 1905, aged 55 died, July 12, in Hot Springs National Park Ark, of heart disease

**George W Wallis**, Fayetteville, Ga, Atlanta Medical College, 1886, member of the Medical Association of Georgia, aged 72, died, June 17, of diabetes mellitus

**John Ralph Good**, Chaplin, Sask, Canada, University of Manitoba Faculty of Medicine, Winnipeg, 1919, aged 41, died May 3, in a Moose Jaw (Sask) hospital

**Thomas E Alyea**, Earlville, Ill, College of Physicians and Surgeons, Keokuk, Iowa, 1880 also a druggist aged 81, died June 15, of shock, as the result of a fall

**John J Comer**, Willis, Kan, Rush Medical College, Chicago, 1893, member of the Kansas Medical Society, aged 67 died, May 15, of carbolic acid poisoning

**John Julius Rudolph**, Hoboken, N J, Baltimore University School of Medicine, 1898, aged 57, died suddenly May 25 in Roselle Park, of heart disease

**J Emile Daigneault**, Sherbrooke, Que, Canada School of Medicine and Surgery of Montreal, 1912, aged 48, died July 11, of coronary thrombosis

**Warren Brown Hill**, Mount, Va, Baltimore University School of Medicine, 1892 aged 72, died, May 13, of carcinoma of the neck, chest and abdomen

**Solomon Francis Rudolf**, Green Bay Wis Northwestern University Medical School, Chicago, 1905, aged 54, died, May 15, of cerebral thrombosis

**George Townley Pryor** ♂ Sheffield Pa University of Buffalo School of Medicine, 1882, aged 74, died, May 26, of chronic myocarditis

**Leon M Prichard**, Catlettsburg, Ky, Hospital College of Medicine, Louisville, 1897, aged 61, died, May 17, of chronic myocarditis

**Matthew M Hill**, Winfield, Kan, Rush Medical College, Chicago, 1901, aged 63, died, July 6, of cerebral hemorrhage

**George Oscar Pratt** ♂ Detroit Detroit College of Medicine 1905, aged 67, died, June 5, of carcinoma of the stomach

**Andrew J Coey**, Chicago, Chicago Medical College, 1880 aged 76, died, June 29, of carcinoma of the larynx

## MISBRANDED "PATENT MEDICINES"

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

[EDITORIAL NOTE The abstracts that follow are given in the briefest possible form (1) the name of the product, (2) the name of the manufacturer, shipper or consigner, (3) the composition, (4) the type of nostrum, (5) the reason for the charge of misbranding and (6) the date of issuance of the Notice of Judgment—which may be considerably later than the date of the seizure of the product]

**Collins Plasters**—Potter Drug & Chemical Corp Malden Mass Composition Essentially oleoresin of red pepper, starch and rubber spread on a cloth fabric attached to two metal strips one of zinc the other of copper For rheumatism weak back stomach cramps simple bone fractures etc Fraudulent therapeutic claims—[N J 20568 February 1934]

**St John's (I L) Magnetic Brand Oil**—Frank L Bridinger Tiffin Ohio Composition Essentially small amounts of turpentine oil and rosin with chloroform alcohol and water Cure all Fraudulent therapeutic claims—[N J 20571 February 1934]

**Silrizol**—Sturizol Co Inc Ossining N Y Composition Essentially borax and common salt with small amounts of essential oils including menthol thymol eucalyptol and methyl salicylate Not antiseptic as vaginal douche as claimed Fraudulent therapeutic claims—[N J 20574 February 1934]

**Menthymol**—Crezoin Chemical Co Merchantville N J Composition Essentially petrolatum and liquid petrolatum with 25 per cent of volatile oils including menthol thymol and eucalyptol For asthma hay fever bronchitis tonsillitis etc Fraudulent therapeutic claims—[N J 20575 February 1934]

**Crezoin Balsam Formula No 1**—Crezoin Chemical Co Merchantville N J Composition Essentially an alcoholic solution of volatile oils including menthol and eucalyptol with gums such as benzoin and tolu and crocote For asthma hay fever bronchitis tonsillitis etc Fraudulent therapeutic claims—[N J 20575 February 1934]

**Rawleigh's Rheumatol Tablets**—V T Rawleigh Co Freeport Ill Composition In each tablet potassium iodide (0.06 gram) sodium salicylate (0.03 gram) and plant drug extract Fraudulent therapeutic claims—[N J 20579 February 1934]

**Moses' Herb Expecto-rant**—Moses Remedy Co Cambria Va Composition Essentially extracts of plant drugs including horehound and wild cherry with sugar and water For coughs croup asthma bronchitis etc Fraudulent therapeutic claims—[N J 20583 February 1934]

**Moses Herb Discovery**—Moses Remedy Co Cambria Va Composition Essentially extracts of plant drugs alcohol (72 per cent by volume) sugar and water For asthma blood diseases female disorders tuberculosis etc Fraudulent therapeutic claims—[N J 20583 February 1934]

**National Yeastolized (Medicated) Salt**—National Feeders Corporation Tiffin Ohio Composition Contained little if any yeast cod liver oil or epsom salt and no potassium iodide Adulterated because below the professed standard under which it was sold and misbranded because of false and misleading statements as to composition—[N J 20584 February 1934]

**O K Lax**—Live Food Products Co Hollywood Calif Composition Essentially ground leaves barks roots and fruits including a laxative drug For catarrh asthma diabetes etc Fraudulent therapeutic claims—[N J 20587 February 1934]

**Grissold's Family Salve**—Sisson Drug Co Hartford, Conn Composition Essentially a lead compound such as lead oleate and rosin For skin ulcers tumors ague etc Fraudulent therapeutic claims—[N J 20588 February 1934]

**A C H Ku Rill**—A C Hynd Corporation Buffalo N Y Composition Essentially small amounts of common salt carbolic acid amy acetate and acetone alcohol and water colored with a pink dye Germicide Fraudulent therapeutic claims—[N J 20590 February 1934]

**Ka Di Dk Compound**—LeDure Medicine Co Columbus Ohio Composition Essentially extracts of plant drugs including a laxative drug glycerin alcohol and water Cure all Fraudulent therapeutic claims—[N J 20592 February 1934]

**Vans (Billy B) Pine Tree Ointment**—Commercial Laboratories Inc Newark N J Composition Petrolatum small amounts of camphor menthol and pine oil colored with a green dye For catarrh eczema itches whooping cough etc Fraudulent therapeutic claims—[N J 20595 February 1934]

**Yum for Headache**—E L Lax Manufacturing Co Brooklyn N Y Composition Contained in each tablet 2 grains each of phenacetine and aspirin and 1 grain of caffeine For la grippe Fraudulent therapeutic claims—[N J 20593 February 1934]

**Sheppard's Magic Liniment**—C L Sheppard Sanatorium & Remedy Co Findlay Ohio Composition Essentially a light petroleum oil with a small amount of turpentine oil Cure all Fraudulent therapeutic claims—[N J 20600 February 1934]

**Dickson's Compound for the Kidneys and Bladder**—Dorothy Dann Inc Chicago Composition Tablets containing methenamine a laxative drug resins and juniper oil coated with sugar starch and calcium carbonate and colored with iron oxide Fraudulent therapeutic claims—[N J 18085 August 1931]

**Bennett's New Life**—Bennett Medicine Co, Norfolk Va Composition Essentially epsom salt iron chloride, small quantities of podophyllum rhubarb and leptandra, traces of salicylic acid and methyl salicylate with about 91 per cent of water For tonic purposes stomach troubles, etc Fraudulent therapeutic claims—[N J 18087 August 1931]

**Tonall**—Tonall Medicine Co Lancaster Pa Composition Extracts of sarsaparilla senna, uva ursi licorice nux vomica and wild cherry with glycerine alcohol and water For stomach and kidney disorders Fraudulent therapeutic claims—[N J 18092 August 1931]

### ARTIFICIAL RESPIRATION

*To the Editor*—Many lives are being saved annually by the Red Cross and industrial organizations by teaching the "prone, face down method" of artificial respiration for drownings electric shock and asphyxia. However, I believe this method could be made more effective by the simple expedient of placing the head "down hill" when feasible on a 10 to 15 per cent incline, as all physicians know the extreme value of letting the head down in shock on the operating table. The cerebral vital centers get more blood and under increased pressure and the Lewis pendulum swing will often restore when all else fails. Furthermore, the added drainage from the lungs and stomach make it more necessary in drownings.

I have recently performed artificial respiration by this method on conscious people and there is no possible hindrance because of the weight of the abdominal viscera against the diaphragm. I presume that from 1 to 3 per cent more recoveries might be possible by this simple expedient of letting the head down during resuscitation and yet it would not complicate the treatment when it is entrusted to lay people—the mere placing of the body with the head down hill when feasible artificial respiration to proceed nevertheless from the beginning until the inclined position may be effected. All physicians and surgeons with whom I have mentioned this have the same opinion of its added advantage over the level position of the subject.

As these organizations are principally of lay people I believe that the medical profession should carefully consider this expedient and instruct them accordingly.

JAMES G. POE, M.D., Dallas, Texas  
Anesthesiologist, Baylor University Hospital

### STIMULATION OF SUBCORTEX OF THE BRAIN

*To the Editor*—In THE JOURNAL, April 28, appeared an editorial on a new method of physiologic research based on the article of Light and Chaffee (*Science* 79:299 [March 30] 1934). In the editorial you made no mention either of Hess of Zurich, who reported to the International Physiological Congress at Boston in 1929 a method of stimulating the subcortex electrically in more or less normal animals, or of the paper of R. B. Loucks of this laboratory. I enclose a reprint of the latter's work. Loucks described a technique similar to that of Light and Chaffee three months earlier.

W. HORSLEY GANTT, M.D., Baltimore

**COMMENT**—We are glad to refer to the facts in relation to the interesting new procedures that remove the restrictions of time, anesthesia and restraint from experimental explanation of functions susceptible to electrical excitation as described in the editorial "A New Method of Physiologic Research" (THE JOURNAL, April 28, p. 1400). At the Boston meetings of the International Physiological Congress in 1929, Prof. W. R. Hess of the physiologic institute at the University of Zurich demonstrated a method of stimulating the subcortex of the brain. The demonstration is referred to in the abstracts of communications to the congress published in the *American Journal of Physiology* in October 1929, but no details are given. They can be found, however, in a monograph by Hess (Beiträge zur Physiologie des Hirnstammes. I. Teil. Die Methodik der lokalisierten Reizung und Ausschaltung subkortikaler Hirnabschnitte, Leipzig, Georg Thieme, 1932). The scheme consists in the surgical attachment of stimulating devices to the skull of cats. Wires were employed, however,

to connect the animal with the requisite external apparatus. The author stresses the advantage of his technique in the circumstance that the animal is free to move and all ordinary restraint is averted. Cats were used as subjects of investigation. Hess admits that monkeys would be superior but he states that he has avoided this animal because of the large expense involved as well as the highly developed "organization" of the animal, which would afford special difficulties in interpretation. On the other hand, Light and Chaffee, whose work was reviewed in the editorial, have used monkeys with remarkable success and with advantages that must be evident. The principle of "remote control," which the Yale University studies especially stress, differed from Hess's technique in the circumstance that the latter could exercise such influence only through the use of wired electrical connection.

The investigations of Loucks (Preliminary Report of a Technique for Stimulation or Destruction of Tissues Beneath the Integument and the Establishing of Conditioned Reactions with Faradization of the Cerebral Cortex, *J. Comp. Psychol.*, 16:439 [Dec.] 1933), to which our correspondent refers, make no reference to the prior work of Hess, which has just been reviewed. It criticizes the principle of the latter as follows:

In experiments where it is desired to stimulate electrically over a period of weeks tissues located beneath the integument wires brought out through the skin may prove very troublesome. Fine wires are easily broken, heavy wires may induce sloughing or infection. To obviate these inconveniences it has been found feasible to bury a collodion coated coil just beneath the skin and to lead insulated wires from this coil to electrodes located at the point to be stimulated. When the primary of a common laboratory inductorium is laid on the skin external but adjacent to the subcutaneous coil the electromagnetic field passing through the skin induces a faradic current in the collodion coated coil which is transmitted along the insulated leads to the electrodes.

The technique of the Baltimore investigators therefore represents a step in advance, as the inductorium is "laid on the skin" instead of being attached through wires brought through the skin. Dogs have been used as the experimental animal. Proximity of the inductorium to the animal is apparently essential. In the scheme of Light and Chaffee (Electrical Excitation of the Nervous System—Introducing a New Principle: Remote Control, Preliminary Report, *Science* 79:299 [March 30] 1934) the animal is placed within the magnetic field entirely detached and free from the specially designed primary circuit. This fact clearly justifies the designation of their method as a new principle of remote control.

All the newer devices represent a step in the direction of progress in fields that have not been easy to cultivate because of the experimental difficulties involved. There are real merits in all the investigations, and the investigators are deserving of praise. We shall await with interest the reports of the progress made by all the competing procedures.—Ed

### THERAPY OF CONJUNCTIVITIS

*To the Editor*—Permit me to add one or two random, but I think practical hints to the excellent article on the therapy of conjunctivitis by Dr. Sanford R. Gifford in THE JOURNAL, July 7. In the treatment of gonorrheal ophthalmia, of infants and adults, as well, the chlorine compounds are very valuable either as "drops" or diluted, as irrigation fluid. My teacher, the late Dr. Emil Gruening used the official, *Aqua Chlorini (recentur preparata)* diluted to one tenth strength. Today there are the various calcium and soda chlorine preparations, chloramine, surgical solution of chlorinated soda, and so on, which seem to have an almost specific action against the gonococcus. Pressure on the cornea with resultant necrosis is often due at least in part to hot and tensely swollen lids with retention of pus secretion. A liberal tarsotomy may work wonders. Free blood letting does no harm and what might have seemed a desperate remedy is in experience amply justified by the results. In irrigating "babies' sore eyes" pus is apt to spurt, especially when an attempt is made to force the lids apart with the

fingers "It is the physicians' duty to instruct nurses" of this hazard and to advise wearing protective goggles as well as to inculcate the danger of the gonococcus to adult eyes and the need of scrupulous cleanliness both for self protection and to avoid spreading this serious infection. In addition to the other etiologic factors of conjunctivitis mentioned in Dr Gifford's summary, minute foreign bodies should not be forgotten. This should always be thought of and excluded—or eliminated—especially in case of unilateral conjunctivitis. The symptoms are often quite misleading but there are few things a patient resents as much as the overlooking of a foreign body and continued treatment without removal of the cause.

PERCY FRIDENBERG, M.D., New York

### HEAVY METALS IN SYPHILIS

*To the Editor*—The article "Standard Treatment Procedure in Early Syphilis," by John H. Stokes and others (*THE JOURNAL*, April 21), seems somewhat ambiguous on the question of treatment with heavy metals.

On page 1271 the statement is made that "from the data thus presented it appears, then, that the modern treatment of early syphilis should be continuous, and in accordance with the principles generally recognized in the treatment with heavy metal for one year after all symptoms and signs of the disease have disappeared."

The authors can scarcely mean that this would imply, viz., that heavy metal is given for a full year without interruption. Moreover, this is not in accordance with the scheme published on the same page.

Perhaps one of the authors would be willing to clarify this.

FRANKLIN P. PYLES, M.D., Rio De Janeiro, Brazil

[The question was referred to the authors of the article, who reply.]

*To the Editor*—Attention should be called first to the fact that the statement as rendered by the inquirer is a misquotation. The actual wording reads:

The modern system for the treatment of early syphilis must be continuous. It must employ an arsphenamine and a bismuth compound the latter intramuscularly. It must call for not less than twenty and unless special resistiveness is encountered hardly more than thirty injections of the arsphenamine and in accordance with the principles generally recognized in the treatment of the disease the system should call for continued treatment with heavy metal for one year after all symptoms and signs of the disease have disappeared.

Taken in its entirety, this statement means that treatment should be continuous during the period when arsphenamine and bismuth compounds are being used. If after the thirty injection arsphenamine requirement with alternating courses of a bismuth compound is satisfied symptoms of the disease still remain heavy metal treatment should be continued (not "continuous") "in accordance with the principles generally recognized in the treatment of the disease, which means that when a heavy metal is used alone for any purpose there must be an alternation of periods of treatment with periods of rest appropriate to the drug and preparation used, to prevent the development of serious cumulative effects. It was taken for granted that it would not be necessary to explain this elementary principle in the use of heavy metal alone.

Work on this material recently completed indicates that a prolongation of alternating continuous arsphenamine and heavy metal therapy is preferable to the tapering off with heavy metal alone outlined in this presentation. Thus the quoted schedule provides for and the criticism that schedule and text do not exactly correspond must be answered by saying that both are within the range of variation permitted by present known facts and authoritative opinion.

JOHN H. STOKES, M.D. ET AL.

## Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted, on request.

### POSSIBLE INFECTION WITH POLIOMYELITIS AT SWIMMING POOL

*To the Editor*—A 10 year old girl apparently in perfect health, went swimming in a private pool two days before she became ill with anterior poliomyelitis. She died four days after the onset. She had not been out of town and the only other case had occurred one month previously. No new cases have occurred in the ten days since her death. Is it likely that she contracted the disease in the pool? Is it likely that those in the pool with her were exposed? If so, was the virus transmitted through the air by droplet infection or through the water? How long would the virus be active in a pool in which the chlorine is kept between 0.2 and 0.5 parts per million? Have any cases been traced to transmission by swimming pools? Our policy in regard to the pool will be affected by your answer. Please omit name.

M.D., Colorado

*ANSWER*—It is not likely that the patient contracted infantile paralysis from the water in the pool. She may have contracted the disease from contact with carriers at the pool. It is possible that persons at the pool with the patient may have received infection from her by the droplet method. There is good reason to believe that the virus would be destroyed in a short time in the chlorinated water of the pool. So far as is known, cases of infantile paralysis have not been traced to the water in swimming pools.

### PERENNIAL TREATMENT OF HAY FEVER

*To the Editor*—A white man aged 29 came to me in May 1933 with a history of fall hay fever. He had symptoms for the first time in 1932. He was found to be very sensitive to the Ambrosiaceae group and was given eighteen injections between May 15 and September 15. The doses began with 6 units and were increased gradually until he received 3,600 units for the fifteenth, sixteenth, seventeenth and eighteenth doses. I used Parke Davis and Company's Bio 364. He agreed to take a treatment monthly but did not come in regularly receiving doses October 17, December 6, April 13 and June 5. Each of these doses was 3,600 units. He had no symptoms during the regular fall season and had only slight reactions to the other doses. He wants to continue treatment and I should like to know what schedule of doses he should receive. Please omit name and address.

M.D. Iowa

*ANSWER*—The perennial treatment of hay fever is being adopted more and more by most specialists in this field. It has the advantage of keeping up the patient's immunity throughout the year. It is also more convenient for the patient and for the physician, for by its use higher dosages may be reached, should they be desired, than by the pre-seasonal method formerly in vogue. However, in order to be effective, injections must be given more or less regularly, and most men feel that the interval between treatments should be about two weeks rather than a month. This shorter interval markedly lessens the chances of a constitutional reaction, that is, asthma, hay fever or urticaria, or combinations, which may occur after injections of pollen extracts.

It has been noticed that the patient under consideration took injections in October, December, April and June, apparently with no reactions. The fact that he escaped constitutional reactions with such long intervals intervening between injections would seem to point to the fact that either he is only mildly sensitive to the ragweeds (Ambrosiaceae) or else the extract used for injections had deteriorated. Perhaps it was not kept at a sufficiently low temperature. Such long intervals, especially the one between December and April, amounting to more than four months are to be vigorously condemned as they lead to constitutional reactions in most cases in which potent extracts are used.

The question of the proper procedure at this time will depend on the extract used. If the same one is to be injected, the 3,600 unit dosage would probably be all right, and if there is no reaction the dosage may be increased once a week until the hay fever season arrives, that is, about the middle of August. If treatment is to be continued then, which is advisable, the highest dose reached may be repeated once a week until the end of the hay fever season and then once in two weeks all the year round.

If, on the other hand, a new extract is to be used, it is strongly advisable to reduce the dose sharply to not more than 1,800 units at the maximum. The dosage may then be increased once again if no reactions occur. Solutions of epinephrine hydrochloride should always be available in case of a constitutional reaction and the patient should not be permitted

to leave the office for at least twenty or thirty minutes after injections

An average increase of dosage is about 50 per cent, not over. It is better to err on the side of safety than to push the dose too rapidly.

In addition to the series of injections of ragweed pollen extract, it is advisable in all hay fever and asthma cases to have complete skin tests carried out, including pollens, epidermals, foods and miscellaneous substances. About two out of three hay fever cases will give positive reactions to proteins besides the pollens. The elimination of these proteins during the hay fever season will increase markedly the percentage of successful results.

#### PIGMENTATION AFTER BISMUTH THERAPY

To the Editor—I have a 28 year old colored patient with syphilis whom I have been treating with nearsphenamine and preparations of bismuth. Ever since he has been getting the bismuth preparations numerous black spots have appeared in his skin presumably deposits of metallic bismuth. Can anything be done to make these spots disappear? These spots appeared after the fourth or sixth intramuscular injection of bismuth salicylate in oil. I have tried other forms of bismuth in aqueous tartrate solution and also metallic bismuth. In each instance the spots have become more numerous. However there is no evidence of any discoloration of the gums. Apparently the mouth and gums have escaped any deposition. Please omit name.

M D Virginia

ANSWER—In certain papular syphiloderms a pigmentation may be left at the site of the papules after both arsenical and bismuth therapy. Such pigmentation generally disappears within a few months to a year. The query also arises whether the patient has been taking any form of phenolphthalein which may also cause such pigmentation—independently of either syphilis or heavy metal therapy. It is true however that isolated examples of pigmentation of the skin following bismuth therapy of syphilis are reported in the literature. A good review of the subject appears in Jadassohn's *Handbuch der Haut- und Geschlechtskrankheiten* Berlin Julius Springer 18 466, 1928. Courcoux and Boutelier's patient after arsphenamine and bismuth therapy, developed an urticaria which in leaving, left pigmented spots. Quevrat's patient, after bismuth injections, had pigmented spots the size of the palm over the buttocks. Buschke's patient with large papular syphilids, had black pigmented spots several months after on the site of all the former syphilids. Brytscheff's patient with an arsphenamine dermatitis, recovered with a course of bismuth therapy but a strong pigmentation was left as the result of deposits (?) of bismuth in the skin. Feldmann had a similar case in which three months following treatment there were deep brownish black spots. Microscopic examination showed in the subpapillary layer of the skin dark brown masses, which impregnated the endothelium of the vessels and which he took to be deposits of bismuth, but no chemical examination of the deposits was made and it is quite possible that they were simply pigmented cells or granules.

The inquirer's case is interesting and deserves further study. The patient may be treated for the time being with courses of arsphenamine or nearsphenamine and alternating courses of mercuric salicylate injections or mercuryunctions. It would be well to remove sections of skin from such pigmented spots and have them examined by a competent dermatopathologist. Microchemical tests would help much to reveal the true type of pigment present.

#### DIABETES INSIPIDUS IN PREGNANCY

To the Editor—A primigravida woman aged 22 in previous good health has developed diabetes insipidus during the sixth month of pregnancy. She is of the tall thin asthenic type. She drinks about sixty glasses of water every twenty four hours and passes from  $3\frac{1}{2}$  to 4 gallons of urine during this time. A stereoreontgenogram of the skull shows no deepening of the sella turcica. The blood sugar is normal. Posterior pituitary powder intranasally has thus far not controlled the symptoms although treatment has been started and the dosage will have to be increased. What complications if any can one expect at the time of labor? Would there be any tendency to hemorrhage after the placenta is delivered through inability of the uterus to contract owing to this condition? Would this condition tend to diminish the severity of the uterine contractions? And should any other treatment be given in addition to postpartum extract? Please omit name and address.

M D California

ANSWER—Diabetes insipidus is extremely rare during pregnancy, and individual cases are worthy of being reported. The textbooks by De Lee and Williams and the large system of Halban and Seitz on the biology and pathology of women do not even mention the association of this disease and pregnancy. In women who have diabetes insipidus the genital organs remain

morphologically and functionally intact unless there are gross changes in the hypophysis. Hence there should be no difficulties during pregnancy, labor or the puerperium. This is borne out in the few reported instances. In the case reported by Anselmino and Hoffman (*Zentralbl. f. Gynak.* 54 2061 [Aug. 16] 1934) the patient was afflicted with diabetes insipidus during two pregnancies and was free from the disease between gestations. Aside from the excessive thirst and the extraordinarily profuse output of urine, the patient had no discomforts. Labor was uncomplicated both times. The first child died for an unknown reason shortly after birth but the second, born at full term, remained alive and healthy. The subjective and objective symptoms of the diabetes insipidus disappeared suddenly during the first few days of the puerperium. In the case reported by Artaud (*Bull. Soc. d'obst. et de gynec.* 22 196 [Feb.] 1933) labor started spontaneously at seven and a half months and was quickly completed. The only complication was a laceration of the fourchette in spite of the fact that the fetus weighed but 1,300 Gm. The author attributed the tear to dryness of the tissue due to the elimination of large amounts of fluid from the body. The puerperium was normal and the symptoms of the diabetes insipidus disappeared after labor. Theoretically there is danger of starting premature labor by administering posterior pituitary hormone. Artaud purposely avoided giving his patient solution of pituitary because of this fear, yet his patient had a spontaneous premature termination of pregnancy. In addition to giving posterior pituitary preparations, it is advisable to administer soporifics, so that the patient's sleep may not be disturbed much by urination. Prophylactically posterior pituitary substance should be given immediately after delivery of the baby.

A few years ago, Hann expressed the view that in diabetes insipidus there is not only an insufficiency of the posterior hypophysis but also a disturbance in the function of the anterior hypophysis. Jacobi elaborated on this idea and came to the conclusion that there was an antagonism between the anterior and posterior pituitary lobes in controlling the water balance of the body. If the function of the anterior pituitary lobe increased unduly, diabetes insipidus resulted. In the case reported by Anselmino and Hoffman, the disease disappeared suddenly on the fifth day. This is the day on which the Aschheim-Zondek pregnancy test usually becomes negative following labor and indicates the day on which the increased activity of the anterior pituitary lobe ceases.

#### ARTIFICIAL INSEMINATION

To the Editor—I will appreciate it if you will give me all the details of the best and most practical method of performing artificial insemination. Please omit name.

M D

ANSWER—Before undertaking insemination it is important to make a careful pelvic examination to rule out the presence of infection in the vulva, the vagina, the cervix or the fallopian tubes. Of course insemination should not be performed in the presence of any infection. Furthermore, before resorting to this procedure it must be certain that the tubes are patent and this can readily be determined by the Rubin test. Assuming that the wife is suitable for insemination, a careful examination of the spermatozoa must be made to be sure they are viable. Furthermore, there must be no evidence of infection in the semen.

The husband and wife should be informed that attempts to impregnate the woman artificially will most likely have to be carried out many times over a period of months. Even then there may not be a successful result. The most favorable time to carry out this procedure is the ten days midway between the first day of one menstrual period and the first day of the next expected menses. The ideal time for conception to take place is at the time of ovulation, which usually occurs about midway between menstrual periods. Since ovulation may occur any time from the tenth to the eighteenth day of the cycle and since the exact day for any particular woman cannot as yet be determined definitely, it is advisable to inseminate three four or five times during these ten days. The husband should be instructed to wash the penis with soap and water before coitus and the wife should take a sodium bicarbonate or salt water douche. There are four methods of procuring semen: masturbation, coitus interruptus using a small jar, coitus condomatus and natural coitus followed by aspiration from the vagina. The most aseptic method and the one that is not too obnoxious, is to have a small sterilized jar at hand before intercourse. At the time of the orgasm the semen should be ejaculated into the jar. The latter should be kept moderately warm or cool and immediately brought to the physician's office. The patient is placed in the lithotomy

position as for a vaginal examination and the vagina is carefully cleansed. The cervix is exposed with a bivalve speculum and the external os is further cleansed. However, it is not advisable to apply any antiseptic, because this may destroy the spermatozoa that are to be injected. The cervix is grasped with a tenaculum, and a uterine cannula is gently inserted into the uterine cavity. The semen in the jar is drawn up into a luer syringe and 1 or 2 cc of it is deposited in the uterine cavity very slowly. If the semen is injected too quickly it will be expelled by uterine contractions. After the injection is performed, the cannula should be removed slowly and the patient should be quiet on the examining table for about thirty minutes. It is best to examine some of the semen just before each insemination to make certain that it is satisfactory.

#### ANGINAL PAIN

*To the Editor*—A man aged 70 has a mitral musical murmur of the heart. The heart is only slightly enlarged. The blood pressure is normal. He has had pain in the chest for the past four years. He speaks of it as a soreness in the chest rather than a pain. He has been taking glyceryl trinitrate tablets for relief. Also diathermy is being used over the chest 1 000 milliamperes for a period of thirty minutes once or twice a week which appears to give some relief. About half an hour after eating even though he is not exercising the discomfort comes in the chest. Please explain the probable cause of pain at this time. Will you also advise as to the best treatment and what value and benefit might one expect from surgical treatment.

THEODORE DODD M.D. Steubenville Ohio

**ANSWER**—The symptoms complained of are probably due to attacks of angina pectoris and do not necessarily bear any relation to the mitral lesion. Anginal pain is often described as a "soreness" and need not be either acute or severe. Such pain is more prone to occur after meals. It is assumed to be due to a blood supply to the heart that is inadequate for the needs at the moment. Such a change in the blood supply may be due to vascular disturbances in the heart muscle or to a decrease in the coronary flow resulting from coronary vasoconstriction or may be due to passive changes in the coronary flow consequent on changes in the systemic blood pressure.

The patient should be placed on an easily digestible diet and one that will not cause gas. He should be instructed to rest before meals and to rest for an hour or so after meals.

As regard medication, the use of the purine base diuretics is to be advised. They offer a greater probability of help than any other medication. They tend to dilate the coronary vessels and to increase the coronary flow. Their continued use has been shown by Smith to increase coronary anastomoses and collateral circulation. They do not relieve pain but they tend to improve the underlying condition. Their use should be persisted in for months, even if no relief is experienced at first. They are best taken during the meals, to avoid untoward symptoms.

#### QUARANTINE IN SCARLET FEVER

*To the Editor*—A child with scarlet fever develops an otitis media which is further complicated by a mastoiditis. The mastoid cells are drained by operation. The child slowly improves but has a purulent discharge for several months. At what time during this period of convalescence do you consider it safe to release this child from quarantine so that other children can come to the home and this child be allowed with safety to enter other homes? Please omit name.

M.D. Illinois

**ANSWER**—Health authorities insist that scarlet fever patients shall be quarantined until all discharges, including those from the ear, have ceased. There is no arbitrary time after which ear discharges following scarlet fever are free from danger. Disastrous outbreaks of scarlet fever have resulted from the introduction of a patient with such a discharge which had persisted many months, into a group of susceptible children. The infectious property of the discharge resides in the specific scarlet fever streptococcus. So long as it is present, the discharge is a source of danger. Its presence can be determined only by a bacteriologic examination. When cultures from the discharge on blood agar plates no longer show colonies of hemolyzing streptococci it may be considered that the danger is over. These negative cultures must be secured several days in succession and caution must be used not to make the cultures near the time when antiseptics have been introduced into the ear. While not all hemolyzing streptococci are scarlatinal in the absence of facilities for testing their specific character, as shown by their serologic reactions and toxin production those in discharges which follow scarlet fever must be considered as probably specific.

#### CARBON DISULPHIDE POISONING—DERMATITIS FROM FORMALDEHYDE

*To the Editor*—A local concern, which manufactures caps for bottles made from cellulose the process being similar to that used in the manufacture of rayon, is having trouble with the men who work in the "viscose" department of the plant. After the wood fiber sheets are removed from the shredder they are put in a constant temperature room for two days and then into a tank containing carbon disulphide. The workmen complain of becoming dizzy, their heads seem to swell, a numbness and tingling sensation spreads to the hands and down the legs to the feet, and they feel as though they were drunk. This sensation soon passes off if they can get out into the open air but it has created a marked mental reaction in three of the men in that they have a perfect horror of returning to the job. In fact, one man left the work and has never returned even for his pay. I have talked to several of the men in regard to this fear and they seem at a loss to explain this reaction. One man however stated that he believed it was merely his nerves. I was talking to the wife of one of the men who has been in this department for about two months and she said that her husband had become increasingly irritable and had lost his appetite and did not sleep soundly at night. This particular man stated that the main reaction was his dread of returning to work for his shift stating that he would do almost anything if he did not have to go back to that smell again. I went out to the plant and inhaled enough of the gas as to experience the same sensation and I found that it was similar to the inhalation of ether and gave me a sensation like that of an ether jag. In the *American Journal of Public Health and National Health* (20: 598 [June] 1930) is discussed the hazards of hydrogen sulphide in industry. I presume that the effects from carbon disulphide are similar to those produced by hydrogen sulphide. As the company is building a new plant and is anxious to safeguard the employees in this department I would appreciate any information you can give me in regard to the prevention of this poisoning and the treatment especially of these nervous mental symptoms. In another department where girls work to sort cut and pack the finished caps there has been a skin disorder that has proved most annoying. These girls are handling wet cellulose caps which have been soaked in a solution of water, glycerin and about 1 per cent formaldehyde. They first notice patchy, papular eruptions usually occurring on the backs of the hands between the fingers and on the lower third of the forearms. These patches vary in size from the head of a large pin to areas about 30 mm in diameter. These patches consist of small bright red papules which itch to a moderate degree and then may disappear except between the fingers where the skin becomes indurated, fissured and quite painful. I have never seen the primary lesion as I have but recently been asked to help out with their difficulty nor have I seen the conjunctivitis, which I believe is similar to the "gas eyes" found in workers exposed to hydrogen sulphide. This condition responds readily to treatment, I understand but necessitates the employee being away from work for two or three days.

M.D. Wis.

**ANSWER**—The first of the clinical pictures presented in the query is quite typical of mild carbon disulphide intoxication but not of hydrogen sulphide as implied. The bizarre mental conditions are not factitious but are at least likely to be genuine. A lengthy literature records a wide variety of manifestations of carbon disulphide poisoning almost as protean as are the results of lead poisoning or syphilis. However, throughout almost all, the dominant feature centers about mental and nervous disorders. In the minor case there may occur nothing more than headache, vertigo, excessive fatigability and transient excitement. In the well established case there may exist definite psychoses with intermittent mania and depression, various neuritides, blindness and marked loss in weight, along with a great variety of other possible features.

As little as one part of carbon disulphide in a million parts of air has been credited with causing minor disturbances. When the concentration reaches only slightly higher levels, clear-cut intoxication is believed to be possible. This places carbon disulphide in the category of highly dangerous industrial poisons.

Obviously, prevention demands the continuous barring of these poisonous vapors from the atmosphere breathed by workers. In the particular industry mentioned in the query, which is only one of several in which this substance may be used, the chief opportunities for exposure are

1 The escape of vapors from the vats wherein the cellulose xanthate is produced.

2 Exposure to vapors connected with the cleaning out of vats, which process must take place at intervals.

3 Leaks from pipes, which leaks readily come about, since carbon disulphide possesses the property of dissolving the greater number of joint sealing materials in common use.

4 Exposure provided at the time of dumping the contents of vats into sewers or partly open systems.

Protection against these various exposures may to some extent be procured through the following steps:

1 Spot suction appliances installed at every point wherever vapors may be introduced into the general atmosphere. The ultimate discharge of such exhaust systems should be such that no carbon disulphide may reenter the workroom.

2 In cleaning out vats workers necessarily exposed should be equipped with positive pressure helmets of such construction

as not to be affected by carbon disulphide. Cork thus may be preferable to rubber.

3 Vat material should be discharged only into completely enclosed systems, which, in turn, discharge this dangerous material at points sufficiently remote so that no injury is to be anticipated. The final test of satisfactory conditions is the actual analysis of workroom atmospheres for the purpose of determining the content of carbon disulphide. No precise standard may be cited as constituting the threshold of danger, but the stand is taken that only a few parts of carbon disulphide, such as 3 or 4, per million of air, have been condemned as dangerous.

The second portion of the query, referring to a dermatitis among workers handling wet cellulose caps, correctly associates this industrial skin disorder with formaldehyde as the cause. Similar outbreaks are known to have arisen in various plants carrying out similar operations. The true chemical dermatitis has in some instances been aggravated and prolonged by the secondary invasion by mycotic organisms. The prevention of this condition is most difficult. The content of formaldehyde should be reduced as far below 1 per cent as is consistent with technical requirements. Certain portions of the work may be carried out under glass frames, closed on three sides and equipped with exhaust systems. This may prevent the escape of irritating gases such as might affect the eyes but manifestly will not greatly protect the hands of workers directly in contact with the wet solution. Some workers are far more sensitive than others, which fact, for their own good, should lead to their exclusion from this employment. Brunette types ordinarily are less susceptible. Much would be gained if formaldehyde might be eliminated through the substitution of some less irritating substance meeting the technical requirements for which the formaldehyde is employed.

#### METAPHEN IN PEPTIC ULCER

To the Editor—What is the latest teaching concerning the treatment of peptic ulcer with 1:2500 metaphen solution? When is it best administered?

M. L. SLATE, M.D., High Point, N. C.

ANSWER—C. M. Trippe published in the *Annals of Internal Medicine* in January 1933 a report on the oral administration of metaphen in the treatment of eighty-two cases of peptic ulcer. He administered from 3 to 4 cc of 1:500 solution three times daily before meals for gastric ulcers, and after meals for duodenal ulcers. The patients all suffered from psychoneuroses in addition to their organic trouble and the author reports relief of the mental symptoms as a result of the direct attack on the gastro intestinal lesion. He also states that no toxicity was demonstrated even after the use of as much as 16 cc of 1:500 solution daily for months. Large traces of mercury were found in the stools and none in the urine or blood. There is no definite proof at present that metaphen has any unusual advantages in the treatment of peptic ulcer, and more thorough trial must be made before any recommendation can be given for its therapeutic value. This article asserts that twenty-seven cases show roentgenologic evidence of ulcers and disappearance after the use of metaphen. If this statement is true, one should seriously question the efficacy of any treatment, because it is well known that roentgenologic evidence of duodenal ulcer is not materially altered by treatment of any kind except for relief of associated spasm.

#### INDUSTRIAL HAZARDS IN THE MANUFACTURE OF EXPLOSIVES

To the Editor—Will you kindly send me a report of industrial results of handling explosives such as trinitrotoluene as required in government work at the Savanna Ordnance Depot (Illinois)?

GEORGE H. COTTRAL, M.D., Savanna, Ill.

ANSWER—The extent of information implied in this query exceeds the space limitations of Queries and Minor Notes. If the reference to "industrial results" contemplates only the possible ill effects on the health and well being of exposed persons, still it is to be recognized that a varied lot of little related problems arise. These embrace, among others, the nature and toxicity of gases produced after detonation, the results of concussion on the auditory organs and other tissues, the nature and extent of accident hazards, the action on the body of the products of the slow decomposition of explosives and the effects of various chemicals used in the reclaiming of damaged lots of explosives. If, in fact, any explosives are manufactured, the most important consideration of all is to be directed to the intermediates employed, such as toluene.

Information of this character in extended form appears in many federal publications. A communication directed to the Commanding Officer of Edgewood Arsenal, Edgewood, Maryland, setting forth requests for specific information will lead to the citation of pertinent publications that are available through the Superintendent of Public Documents, Washington, D. C. In any urban library there is likely to be available listings year by year of scores of governmental publications bearing on the topics covered by this query.

#### TRYPARSAMIDE IN SYPHILIS OF THE OPTIC NERVE

To the Editor—I am fully aware of the fact that tryparsamide is said to be contraindicated in optic atrophy. However in view of the fact that syphilis of the optic nerve is a progressive disease which eventually terminates in blindness would it be justifiable to use this drug in a case presenting failing vision of the left eye for the past three years with the restlessness irritability forgetfulness and impaired judgment of the patient with dementia paralytica and the physical signs of external strabismus of the left eye weakness of the left internal rectus vision decreased in the left eye until only light is perceived and visual acuity zero in the left eye? The visual acuity of the right eye is 20/20. The pupils are fixed to light. The fundi show primary optic atrophy more advanced in the left eye and other neurologic signs and the spinal fluid are indicative of dementia paralytica. The patient has been placed on malaria therapy with no improvement in vision. In the past he has had intensive courses of arsphenamine bismuth compounds and intra spinal therapy (the exact nature of the latter is unknown) with continued progression of the disease process in the left eye. Swift Ellis treatment is not available. 1 In view of the fact that Woods and Moore have shown improvement with tryparsamide in cases of optic atrophy provided weekly examinations of the visual fields visual acuity and fundi are taken and the preliminary subjective complaints of sensitivity to the drug watched for would it not be wise to use tryparsamide in this case?

2 What is the present status of the Swift Ellis treatment in the treatment of neurosyphilis, especially optic atrophy? 3 Have any benefits been observed from the use of fever therapy in arresting optic atrophy? 4 Is there any other treatment that you could suggest to arrest advancing impairment of vision and perhaps restore sight? 5 How would you differentiate clinically between spasticity or rigidity of extrapyramidal origin and pyramidal tract disease? What are the characteristic signs and symptoms of each? It is the belief of most investigators that the benefit in dementia paralytica is due to the fever induced by malaria. However, several cases have been reported in which remissions have occurred with malarial therapy and without any appreciable rise in temperature the parasites however being found in the blood stream. I would appreciate any references on the subject.

W. W. PIKE, Binghamton, N. Y.

ANSWER—1 Under the conditions, it would not be unwise to use tryparsamide.

2 There is no known treatment which can cure optic syphilitic atrophy.

3 No.

4 No.

5 In pyramidal tract disease the Babinski reflex should be present. Extrapyramidal rigidity is characterized mainly by tremor and rigidity.

The benefits derived from malarial therapy are thought to be mainly due to the rise of the temperature and its persistence.

#### CRAMPS IN LEGS

To the Editor—A man aged 43, who had sciatica in youth but not severely after the age of 18 went on a mountain climb four years ago which was an unusual experience. After traveling about five hours he suffered very severe cramps in both legs which subsided after half an hour's rest. He succeeded in completing the trip a mile and a half more by resting every few rods. Since that time he has had pain with weakness and occasional stiffness in the muscles of both legs extending from the middle third of the thighs to the middle third of the legs which seems most painful anteriorly in the thighs and posteriorly in the legs. It is accompanied at times by considerable weakness and fatigue in the knee joints. The condition is persistently better in the mornings and worse in the latter part of the day although a period of forced rest of two weeks in bed did not result in improvement. The patient's arteries seem normal for his age, his blood pressure is inclined to be low and all other systems seem normal. Tobacco and alcohol have never been used and the blood Wassermann reaction is negative. Treatment has consisted of salicylates which seem to help temporarily and hydrotherapy which has helped little if at all. The patient has felt that he is better after dancing but worse after exercise that involves stooping, lifting or pushing. Is this intermittent claudication or myostitis and what curative treatment preferably local treatment can be relied on? Please omit name.

M. D., Washington

ANSWER—The pains of intermittent claudication, which are characteristically induced by uninterrupted walking disappear promptly on cessation of this activity. They do not occur while the patient is at rest or as a result of prolonged periods of standing or of interrupted walking short distances as exemplified by the activity of a clerk in a store. It is highly improbable that the symptoms described are those of intermittent claudica-

tion, although the correspondent fails to state the relationship of the distress to walking. If pulsations in the dorsalis pedis, posterior tibial and popliteal arteries are normal, the distress is certainly not that of intermittent claudication.

The symptoms mentioned may be evidence of a general exhaustion state such as neurasthenia or chronic nervous exhaustion. The patient may have peripheral neuritis due to lead, arsenic or diabetes or he may have an inflammatory lesion or compression of the lumbosacral plexus. Arthritis of the spine might be responsible. If examination fails to disclose evidence of the conditions mentioned, it is a fair assumption that the distress originates in the muscles. The teeth, tonsils and prostate gland should be examined for evidence of infection, which should be eradicated if present. A vaccine made from organisms present in these areas may be of value. The local application of heat by an electric pad, the ordinary baker in which the source of heat is carbon filament electric light bulbs, or any of the various electrical devices for this purpose may be of distinct value. Massage is indicated, and rubs with warm methyl salicylate may give symptomatic relief. If the distress is mild, the regular administration of anodynes such as acetophenetidin or acetylsalicylic acid may increase the comfort of the patient. The intravenous injection of typhoid vaccine in amounts of from 10,000,000 to 25,000,000 killed organisms may be beneficial in a nonspecific manner.

#### TREATMENT OF BURNS

*To the Editor*—I would appreciate your advising me regarding the method of treating burns with horse serum, the merits of substituting cow serum for horse serum in such treatment and the method of producing a sterile cow serum provided a cow serum can be beneficially used.

CARL A. LINDBLAD, Providence, R. I.

**ANSWER**—The use of horse serum in the treatment of granulating wounds following burns was first advocated by E. P. Robinson in 1917. The technic consists of spraying the margins of the wound with normal horse serum and then covering the treated areas with rubber tissue. This procedure is repeated several times daily. After ten days, epithelization should be well advanced and treatment may be discontinued. Robinson states that tricesol, which is used as a preservative, may be safely omitted from the serum if tubes containing only enough serum for a single application are used. Omission of the tricesol prevents painful smarting during the spraying process and, he believes, possibly accelerates cell proliferation.

Horse serum is advocated on the theory that it provides nutrition to growing epithelial cells. If this theory is correct, there is no reason why cow serum cannot be used.

Serum should be collected under strictly aseptic conditions and may be preserved by the addition of 0.3 per cent tricesol. Before this method of treatment is tried it would seem logical to determine by means of skin tests whether or not the patient is sensitive to the serum that it is proposed to use.

#### TREATMENT OF ELECTRICAL SHOCK

*To the Editor*—Aside from artificial respiration and the application of external heat for apparently lifeless victims of electrical shock, what other treatment is indicated and contraindicated? In a recent discussion of this subject the manager of the local light and power company stated that the latest information sent by the safety council advised against the use of any hypodermic stimulants in these cases on the ground that such stimulants might have a paralyzing effect on the heart and respiratory centers. It has always been my opinion that caffeine, epinephrine and other cardiorespiratory stimulants were indicated in cases of this type. What drugs are indicated and contraindicated in cases of asphyxiation from ammonia? Can you give me any references on these two subjects? Does the U. S. Bureau of Public Health publish any information on these subjects? Please omit name.

M. D., Missouri

**ANSWER**—In a forthcoming article in *THE JOURNAL* on resuscitation, sponsored by the Council on Physical Therapy, all subcutaneous, intravenous or intracardiac medication is expressly disapproved. It is recommended that measures of resuscitation be confined to artificial respiration, inhalation of carbon dioxide (7 per cent) and oxygen, external heat cautiously applied and absolute rest. Respiratory stimulants are generally cardiac depressants, and cardiac stimulants are not really beneficial. Immediate reactions may be induced stimulating recovery, but the patient is the worse for them next day.

After exposure to an irritant gas, absolute rest is the measure of prime importance, supplemented by inhalation of oxygen, without carbon dioxide, if the patient is cyanotic. After exposure to ammonia edema of the glottis may necessitate intubation or tracheotomy.

#### EFFECTS OF PERMANENT WAVING ON HAIR

*To the Editor*—Will you kindly let me know whether so-called permanent waving of the hair or repeated setting of the hair is considered harmful to the hair or scalp? Kindly omit name.

M. D., New York.

**ANSWER**—Permanent waving is accomplished by the application of a solution of ammonia, which softens the hair. Heat is then applied to fix the hair in the position desired. This process necessarily dries the hair and tends to make it brittle, the amount of such damage depending on the skill of the operator.

Setting the hair by the use of a mucilaginous preparation is a much simpler process, which causes no such drying.

If these procedures interfere with the daily vigorous brushing of the hair, which is the best form of scalp massage, they may to that extent be harmful. If the patient's scalp should become sensitized to the ammonia solution or to one or more of the ingredients of the "setting" preparation, great damage may be done, but this cannot be held as an objection to the cosmetic process, for it can occur from any contact of a foreign substance with the skin.

#### TUBERCULIN TEST

*To the Editor*—Will you kindly describe the preparation of tuberculin for intracutaneous testing from old tuberculin? Please omit name.

M. D., Ontario

**ANSWER**—Old tuberculin may be secured in concentrated form from drug houses. Before it is used in the intracutaneous test it must be diluted. One part of tuberculin to 9,999 parts of physiologic solution of sodium chloride is the dilution in most common use for the first test. Of this dilution, 0.1 cc. contains 0.01 mg. of old tuberculin. Many workers prefer to use 1 part of tuberculin to 999 parts of physiologic solution of sodium chloride as the initial dose, 0.1 cc. of which contains 0.1 mg. of tuberculin. When the test is negative, whether one uses 0.01 or 0.1 mg. of old tuberculin, a second test is usually performed with 0.1 cc. of a dilution of one part of tuberculin to ninety-nine parts of salt solution. This contains a full milligram of tuberculin. If there is no reaction to the test in forty-eight hours, one is reasonably safe in concluding that tuberculosis does not exist. However, the test is not infallible. Therefore, when there are other reasons to suspect tuberculosis, such as demonstrable evidence of extensive pathologic changes or severe toxemia, one should gradually increase the amount of tuberculin until the final dose contains 5 or 10 mg.

Unfortunately, tuberculin in such weak dilutions deteriorates rather fast. Therefore a fresh preparation should be made every two weeks. To this it is well to add 0.25 per cent of phenol. Tuberculin is inexpensive, and many physicians find it convenient to have a standing order with their pharmacists to prepare and deliver to them as many cubic centimeters as are needed every two weeks. In some cities and even some states, tuberculin in the proper dilution is provided free to physicians by the health departments.

The new tuberculin, which the Research Committee of the National Tuberculosis Association plans to have ready for distribution before long, promises to be more specific than the old tuberculin now in common use and to be in such form that it may be easily and quickly diluted in the physician's office.

#### CONVULSIONS AND BRAIN LESION

*To the Editor*—I have under my care a man aged 30, single. As far as I can ascertain his personal and family history are negative. I first attended him in June 1933, my diagnosis being grand mal. He had never had any previous attacks. The attacks occurred on the average of one a month until recently when they have been coming at weekly intervals usually after breakfast. He was referred to a reputable clinic in Portland, Ore., where a roentgenogram of the skull, blood and spinal Wassermann tests and metabolic tests were made. All reports were normal. The patient's tonsils and infected teeth have been removed. The blood pressure has persistently remained from 112 to 115 systolic. He is now on a ketogenic diet and phenobarbital compound as medication. Would you kindly advise me as to what else I can do to give relief? Please omit name.

M. D., Oregon

**ANSWER**—In the case of any patient over 20 years of age and in this case particularly at the age of 30 years it is hardly possible that the convulsions are due to idiopathic or essential epilepsy, if the history as given is accurate and reliable. It is much more likely that the grand mal seizures are caused by a brain lesion. This may be a tumor, a cyst or a localized encephalitis due to a number of possible causes, including syphilis. There is a possibility also that the seizures may be due to a low blood sugar, and it would be advisable to obtain blood examinations before breakfast on several occasions and,

if possible, a blood sugar examination on a specimen obtained at the time of the seizure. Examination of the fundi should be made by a competent ophthalmologist. The ordinary roentgenogram of the skull would not show a great deal unless there was intracranial pressure, an encephalogram would be much more valuable. The patient should be examined at regular intervals for signs of a developing intracranial lesion. In the meantime the ketogenic diet may be reduced to as low as 15 Gm of carbohydrate and 0.75 Gm of protein per kilogram of body weight, with the remaining calories in fat to make a total of 2,000 calories. The fluid should be limited to 1,000 cc a day. Unless one is sure of the allowance of vitamins and calcium, it is advisable to give a yeast concentrate tablet three times a day and calcium phosphate from 1 to 2 Gm a day. The phenobarbital is just as effective when given as such in doses of 0.1 Gm as often as necessary to control the seizures unless, of course, undesirable reactions appear. The patient should be relieved of any source of irritation or worry and should be kept in a hopeful frame of mind.

#### SKIMMED MILK AND BANANA DIET

To the Editor—Concerning the article by George A. Harrop on a milk and banana diet for the treatment of obesity (*THE JOURNAL* June 16) I have one further question. Shall the patient continue with 1,000 cc of milk and some bananas during the less restricted periods (in the alternating type of treatment)? Please omit name.

M D New York

ANSWER—The patient is expected to continue with 1,000 cc of milk, and bananas, during the period of less restricted diet except for the substitution of one or two eggs for one or two bananas as the case may be. It is not desirable for further weight to be lost during this period, which should be essentially one of adjustment to the earlier loss during the restricted period. During the less restricted period it is possible to substitute equal portions of other fruits, but most patients do not tire of the banana regimen once they have become accustomed to it. Frequently whole milk is substituted for the skimmed milk during the less restricted periods.

#### LITERATURE ON CASE WORK IN PSYCHOANALYSIS

To the Editor—Will you kindly supply me with information as to the place of publication of two articles mentioned in your timely editorial entitled "An Evaluation of Psychoanalysis" which appeared in the Nov. 18, 1933 issue of *THE JOURNAL*? The articles referred to are (1) a report on 721 cases published by the Berlin Psychoanalytic Institute and (2) a report published four years ago by the commission of the British Medical Association.

GEORGE H. KIRBY, M D New York

ANSWER—1 The report on 721 cases, published by the Berlin Psychoanalytic Institute, can be found in "Zehn Jahre Berliner Psychoanalytisches Institut" (Ten Years of the Berlin Psychoanalytic Institute) published in 1930 by the International Psychoanalytischer Verlag, Vienna.

2 The report published four years ago by the commission of the British Medical Association can be found in the "Report of Psycho-Analysis Committee (supplement to the *British Medical Journal* of June 29, 1929)" published by the Medical Department, British Medical Association House, Tavistock Square, London, W C 1.

#### INCUBATION PERIOD OF RABIES IN DOGS

To the Editor—In your reply to M D North Carolina (*THE JOURNAL* July 21 p 208) it would probably have been more to the point to state that in this country the average period of incubation of rabies in the dog is about fourteen or fifteen days. This statement applies to clinical cases and in such instances there seems to be but little difference in the period of incubation regarding the location of the bite. In a wound of the upper lip the period of incubation may be somewhat less than two weeks.

European writers are occasionally quoted by medical and veterinary writers in this country to the effect that the period of incubation is sometimes from several months to one or two years. It is quite possible that in such instances observations were inaccurate and those making such statements have failed to exclude the possibility of rodent vectors.

J V LACROIX, D V S Evanston Ill

#### PARACENTESIS VERSUS SPONTANEOUS PERFORATION IN OTITIS MEDIA

To the Editor—To your answer to the query on this subject (*THE JOURNAL* March 10 1934 p 790) stating that you are not aware of any statistics showing the advantage of early myringotomy it might interest you that Kerner in the first edition of his *Lehrbuch der Ohrenheilkunde* has two series of cases tabulated on page 107 which distinctly shows the advantage of early puncture. This tabulated list of cases is omitted from the last edition presumably to save space. The statement that early puncture leads to an earlier cure however remains.

J M WEST, M D Allentown Pa

## Book Notices

**Bacterial Infection With Special Reference to Dental Practice** By J. L. T. Appleton Jr. BS DDS Professor of Microbiology and Bacteriology the Thomas W. Evans Museum and Dental Institute School of Dentistry University of Pennsylvania Second edition Cloth Price \$7 Pp 654 with 126 illustrations Philadelphia Lea & Febiger 1933

This book is written for both the physician and the dentist. Its unique purpose is to present the subject of bacteriology, especially the problem of infection, in a language understandable to both. A knowledge of its contents will permit physicians and dentists to discuss a common problem with greater comprehension and will tend to obviate past mistakes and misunderstandings on the part of both professions.

The first portion of the subject matter deals briefly with the morphology, physiology and classification of bacteria. It likewise contains an enlightening chapter on the action and effect of chemicals on microorganisms. An insight of this chapter will permit a more rational use of antibacterial agents in sterilization and the treatment of disease.

Much of the book is devoted to part II in which the subject of infection is discussed. Emphasis is placed on the reaction of the host to the invading micro-organisms rather than on a study of the bacteria themselves. Here the author discusses the mechanisms by which bacteria produce disease and how the host reacts and defends itself by natural, humoral and cellular defenses. An interesting chapter on oral hygiene is included in which attention is called to the increasing recognition of the importance of a clean mouth in the practice of both surgery and medicine.

The practitioner of both medicine and dentistry will find part III exceptionally interesting and helpful. It deals with special infections of the oral cavity and contains a careful analysis of conceptions of dental caries, pulpal infections and periodontal infections. The author enters into a considerable discussion of the pulpless tooth and presents a rather pessimistic opinion of its status. Exception might be taken to the importance attached to the cultural method of determining the condition of the periapical tissue, because of the extreme difficulty of avoiding contamination and thus obtaining a false picture. A histologic study of the root end is much more authentic, even though it means a sacrifice of the tooth.

While the use of French, German and Latin phrases in the text may be annoying to some readers, it is a reminder that the professional language still has its root in these tongues.

The book contains a wealth of references to both medical and dental literature, including foreign textbooks and periodicals, and offers to the student and practitioner a surprisingly complete bibliography on subjects related to its title. As a textbook for dental students it may contain too much detail, perhaps obscuring some of the principles by the thoroughness with which the subject is covered but as a reference book and guide to those with some understanding of this subject it is unsurpassed.

**Leitfaden der einheimischen Wurmkrankheiten des Menschen** Von L. Szidat und R. Wigand Paper Price 15.50 marks Pp 212 with 156 illustrations Leipzig Georg Thieme 1934

This monograph is somewhat unique in that it deals with all the helminthic parasites of man found in a limited region, middle Europe. A table lists 124 parasitic worms found in man, twenty-four of which are found in middle Europe. While six species occur in middle Europe and not in North America, and eleven species rarely occur in America and not in middle Europe, all the principal parasites occurring in America except *Necator americanus* are discussed making the monograph extremely useful for American physicians and students of parasitology. The discussions are brief and to the point containing the gist of recent investigations. For most species the discussions include morphologic descriptions of the parasite, distribution and frequency, life history, mode of infection, clinical and pathologic characteristics, prophylaxis and treatment. At the end of each discussion there is appended a brief set of references to the important literature. As might be expected from the title of the monograph, most of the literature is of Euro-

pean origin. It will interest some to know that the authors list thirteen different diagnostic methods for detecting infestation by worms. Local and proprietary names are frequently used for drugs, and one might have difficulty in finding them in this country. The illustrations are without doubt the best that have appeared in any like work and are for the most part reproductions of original photographs and photomicrographs, with some excellent drawings, the authors having done original work in many different fields of helminthology. It is a welcome relief to see new and original illustrations in a textbook in parasitology, especially when they are from actual photographs of the material. While the work is comprehensive enough for the purpose for which it is intended, it is interesting that reference to the killing of *Trichina* by freezing is omitted from the discussion of prophylaxis in trichiniasis. The monograph will serve as an adequate guide to helminthology throughout the entire temperate zone.

**Bergey's Manual of Determinative Bacteriology. A Key for the Identification of Organisms of the Class Schizomycetes.** By David H. Bergey. Assisted by a committee of the Society of American Bacteriologists. Robert S. Breed, Frank M. Hinton, Bernard W. Hammer, E. G. D. Murray and Francis C. Harrison. With an index by Robert S. Breed. New York: Agricultural Experiment Station. Fourth edition. Cloth. Price \$6. Pp 664. Baltimore: Williams & Wilkins Company, 1934.

Whether bacteriologists agree or not with the classification and nomenclature of organisms as published in this manual, they accept the work as an effort in the right direction. This edition which is larger than the third edition by nearly a hundred pages, contains about fifty new species. Recognition has been given to the genus *Brucella* and the genus *Listeria*, while the genus *Pfeifferella* has been combined with the genus *Actinobacillus*. Description of species has been amplified in three genera: *Leuconostoc*, *Propionibacterium* and *Bacteroides*. In all there are 1178 organisms described in the book, indexed both by new and by old names. The manual is recommended to all laboratories doing bacteriologic work.

**Einheitliche Grundlage für die Diättherapie des Diabetes mellitus.** Von Dr. I. Normand. Paper. Price 4.50 marks. Pp 77 with 6 illustrations. Leipzig & Vienna: Franz Deuticke, 1934.

Starting out with the idea that the diabetic diet has been largely empirical, based on no unitary foundation, extremely complicated and often contradictory, the author presents what he considers to be a single theoretical basis for various successful dietetic procedures of the past and its practical application today. His unitary principle is none other than fasting or the more or less complete exclusion of one or two of the three main nutrients: carbohydrate, protein and fat, and administration of the remaining nutrient in abundance. Since fasting affects the diabetic state most favorably and since carbohydrate, protein and fat are all 'diabetogenous,' the first two directly and the latter at least in an indirect fashion, as a successful go-between from hunger to a normal diet, the author resorts to a diet with only one or at times two of the nutrients, but which one or which two is a matter of indifference. He considers that the withdrawal of all food or of one or two nutrients rests the organism and thinks he has proved this by feeding experiments in which equal caloric food values were given with one or two foods instead of three. And not to overburden the organism too long with a one-sided diet he adopts a cyclic system and first gives one nutrient in excess and then another, as he believes that in this way he is alternately resting and stimulating the pancreas and liver.

Although the author appreciates the value of fasting, he does not appear to have quite grasped the fundamental usefulness of Allen's work in that, when one even partially underfeeds a diabetic patient, tolerance for carbohydrate increases or that of Dubois and Richardson, who demonstrated that it is not so much the food which one eats but that which one burns which counts. In other words, in the author's various procedures undernutrition would seem to be far more of a factor in the good results he obtained than the exclusion of one or even two of the chief nutrients. Furthermore, scant attention is paid to the total dextrose value of the various diets. Also one must take issue with the use of alcohol to supply calories on the ground that the effect of alcohol on diabetes is indifferent.

The age of the patients on whom the tests were performed helps to explain the favorable results. Thus ten of the thirteen

patients were over 50 years of age, another was 48 years old and the remaining two were 17 and 15 years, respectively. With individuals of these ages almost any kind of a diet that involves undernutrition, no matter whether high carbohydrate and low fat or vice versa or even a mixed diet, would act well and the author evidently recognizes this because his diets usually contain from 20 to 25 calories per kilogram of body weight. In fact, the patients often lost weight on these diets, but as no nitrogen analyses are given it is impossible to say how lacking the patients were in nitrogen balance.

Notwithstanding these comments, the monograph is interesting and instructive because it shows that now in Europe what F. M. Allen taught in the United States line on line, precept on precept, half a generation ago is recognized and utilized. It explains why the bizarre milk, potato, oatmeal and fruit diets and even the low carbohydrate and low protein with relatively high fat diet of Naunyn, tempered with the restricted calories of Weintraud, the high fat but greatly restricted protein and carbohydrate of Newburg and Marsh here and Petren in Sweden, all worked well after a fashion when applied along with undernutrition in diabetes of moderate severity.

Valuable references to the recent German literature are included in the bibliography.

**The Essentials of Physical Diagnosis.** By Robert W. Buck, M.D., Assistant Professor of Preventive Medicine and Instructor in Physical Diagnosis, Tufts College Medical School. Cloth. Price \$3. Pp. 259 with 21 illustrations. Philadelphia & London: W. B. Saunders Company, 1934.

As the author states in the preface, his purpose in compiling this book has been to introduce the student to the principles of noninstrumental physical examination and to compress this information into a manual that he may carry about with him for reference. This task has been accomplished in a satisfactory manner. Corresponding to the scope of the book, a correlation of individual observations and a description of clinical entities and functional tests have been omitted. The head, abdomen and extremities receive more consideration than in similar manuals on physical diagnosis. Numerous references to original American and foreign sources and a list of titles for supplementary reading are given for the benefit of those who wish more detailed information. An interesting and important chapter is devoted to the body as a whole; it discusses the psychic state, physical constitution, nutrition, posture and gait. Certain omissions have been noticed, e.g., a description of risus sardonicus characteristic for tetanus, the subdivision of dyspnea into inspiratory and expiratory types, boardlike rigidity of the abdominal wall in perforation of gastric or duodenal ulcers or acute pancreatitis, Rovsing's sign of appendicitis, the subdivision of gangrene into dry and wet types, the value of rectal examination in obstetric conditions, and dark urine in obstructed jaundice. The booklet is well adapted for students and compares favorably with other manuals on the same subject.

**La malattia di Heine Medin.** Per il Dott. Luigi Cerza. Paper. Price 30 lire. Pp. 168. Naples: Arti grafiche La Nuova Simma, 1933.

This monograph on anterior poliomyelitis, published as a contribution from the Institute of Pediatrics of the Royal University of Naples, is a systematic treatise. The chapter on etiology is thorough. The author seems convinced that the ultramicroscopic virus isolated by Flexner and Noguchi is truly the specific agent of the disease. He is not inclined to give much importance to the theories advanced that the virus responsible for the poliomyelitis is the same one that is responsible for epidemic encephalitis. Experimental production of the disease in the monkey is well discussed. The epidemiology is treated extensively. The best chapters are those on pathogenesis and pathologic anatomy. The dissertation on the various clinical forms of the disease is excellent. The cases showing the ascending type of Landry and those involving the bulb and the other forms that take on the appearance of diffused myelitis are beautifully treated and without doubt lend a great deal to the understanding of the sequelae that these lesions cause in the patients who recover. One of the benefits of reading this monograph is the reawakening of one's knowledge of neural anatomy and neuropathology. The clinical symptomatology of all the various forms is lucidly described,

particularly in the advanced form of the disease involving the bulb and in other forms involving the midbrain. The therapeutic review is complete and in accord with the most advanced knowledge of the day. The author is convinced of the value of convalescent serum therapy, particularly the serum of recent convalescents, and he recognizes the value of properly prepared antitoxin with the Flexner-Noguchi virus. He regards of doubtful value the serum produced by the streptococcus isolated by Rosenow. The chapter dealing with the physical therapy of the flaccid paralysis is excellent in every respect.

**The Principles of Gynaecology. A Text Book for Students and Practitioners.** By William Blair Bell, B.S., M.D., F.R.C.S., Commander of the Royal Order of the Star of Rumania. Fourth edition revised with the assistance of M. M. Datnow, M.D., B.Ch., F.R.C.S., Demonstrator in Obstetrics and Gynaecology, University of Liverpool, and Arthur C. E. Bell, M.B., B.S., F.R.C.S., Surgeon to Out Patients, Chelsea Hospital for Women. Cloth. Price \$10. Pp. 848 with 507 illustrations. Baltimore: William Wood & Company, 1934.

This authoritative work maintains the general trend of excellence of the previous editions. The author states that no effort has been made to compete with the larger books on gynecology. He casts aside the popular method of compilation and presents in a coherent manner the subject scientifically yet simply, with an imprint of personality. The chapters on internal secretion and certain pathologic lesions, such as endometriomas and ovarian neoplasms, have been rewritten. Discussion of ethical and medicolegal questions and sociological problems, such as contraception, have received consideration. The author is concerned chiefly with the morbid anatomy and his book contains an immense wealth of pathologic material. The operative technic is not described in connection with the corresponding lesions but a special chapter is devoted to surgical procedures. This book has perhaps one fault: while relatively much space is devoted to the fundamental morbid processes, the diagnostic characteristics and therapy are sometimes handled in a step-motherly manner. Few lines are devoted to the treatment of *Trichomonas* infestation; Wertheim's operation is inadequately described; among postoperative measures, intravenous infusions and the use of the indwelling nasal catheter are not mentioned; only the citrate method of blood transfusion is outlined. Discussion of new procedures such as severing nerves for relief of pain in cancer could not be found. The style is fluent. The photomicrographs and colored plates are excellent. The volume will undoubtedly occupy a prominent place in the recent deluge of textbooks on this subject.

**Strophanthintherapie zugleich ein Beispiel quantitativer Digitalisverwendung nach pharmakologischen Grundsätzen.** Von Professor Dr. A. Fraenkel. Unter Mitarbeit von Dr. R. Thauer. Paper. Price 12.50 marks. Pp. 148 with 34 illustrations. Berlin: Julius Springer, 1933.

This concisely and critically written monograph serves a useful purpose, as it not only presents the author's rich personal experience but also summarizes the heretofore scattered data available in the literature on the pharmacologic and therapeutic properties of strophanthin. In most textbooks and monographs on the digitalis substances, strophanthin is, as a rule, treated casually. The author presents briefly the history, botany and chemistry of strophanthin and then proceeds to an analysis of the pharmacology of the drug. He not only describes the well known effect of strophanthin on the heart muscle, on the vagus system and on the conduction system but in one section he emphasizes the fact that chemical substances, such as ions, and physical agents may considerably influence the effect of strophanthin. The fate of strophanthin in the animal organism, as well as the biologic assays used, is well presented. About two thirds of the monograph is devoted to the use of strophanthin in man. Often the effect of other digitalis substances is discussed by way of comparison. The history of the development of intravenous medication is interesting. The beneficial clinical effect of strophanthin in different diseases of the cardiovascular system is analyzed. The author claims that if the single dose administered intravenously is not above 0.5 mg. and if severe diuresis, particularly in older people, is avoided, the danger from serious accidents is practically eliminated. He suggests that some of the fatalities attributed in the literature to strophanthin were probably not due to this drug. Even if some of the American readers

do not agree with free advocacy of intravenous strophanthum therapy, it must be conceded that this work will help to stress the fact that the danger often attributed to the use of strophanthum is at times exaggerated. The extensive and well arranged bibliography makes the monograph also a useful reference book.

**Stoffwechselprobleme** Vorträge aus dem Gebiete der Physio Pathologie gehalten bei der Eröffnung der Sommeruniversität im Palacio de la Magdalena in Santander/Spain. Von Professor S. J. Thannhauser Dr. med. et publ. Direktor der medizinischen Klinik Freiburg i. Br. Paper Price 4.80 marks. Pp 101 with 2 illustrations. Berlin Julius Springer 1934.

This small monograph consists of a series of five lectures delivered by Professor Thannhauser in August 1933. Each lecture is a concise review of a particular metabolic problem from the physiologic, pathologic and clinical aspects. After a rapid historical survey, recent developments are admirably discussed and clinical implications suggested. The lack of a bibliography for the many references to specific pieces of work detracts somewhat from the value of the reviews. The subjects discussed are the formation and metabolism of plant and animal nuclear material, the chemistry of blood and biliary pigments, the site of biliary pigment formation, the genesis of icterus, and disturbances in lipid metabolism. Although Thannhauser has spent many years in the study of these problems and may be regarded as an authority, he does not attempt to stress his personal opinions. These lectures should be of interest and value to the student of internal medicine.

**Die Haut und Geschlechtskrankheiten** Eine zusammenfassende Darstellung für die Praxis. Herausgegeben von Prof. Dr. Leopold Arzt und Prof. Dr. Karl Zieler. Doppel Lieferung 11/12. Band III. Hautkrankheiten tierischer Ätiologie. Von Prof. Dr. Otto Grütz. Die Tuberkulosen der Haut. Von Priv. Doz. Dr. Josef Hämel und Priv. Doz. Dr. Karl Hoede. Benignes Miliariupul. Boeck. Lupus pernio. Leihen nitidus. Granuloma annulare. Erythematodes. Von Prof. Dr. Alfred Stühmer. Lepra. Von Priv. Doz. Dr. Will. Leopold. Sklerom. Malleus. Aktinomykose. Von Dr. Friedrich Fischl. Paper Price 18 marks. Pp 449 738 with 175 illustrations. Berlin & Vienna Urban & Schwarzenberg 1934.

**Die Haut und Geschlechtskrankheiten** Eine zusammenfassende Darstellung für die Praxis. Herausgegeben von Prof. Dr. Leopold Arzt und Prof. Dr. Karl Zieler. Band III. Doppel Lieferung 13/14. Krankheiten der Schweissdrüsen. Von Prof. Dr. Richard Volk. Krankheiten der Talgdrüsen. Von Prof. Dr. Richard Volk. Die Krankheiten der Haare. Von Prof. Dr. Robert Otto Stein. Die Erkrankungen der Nagel. Von Prof. Dr. Robert Otto Stein. Mundschleimhautaffektionen. Von Prof. Dr. Otto Kren. Akute Exantheme einschliesslich der Exantheme bei septischen Prozessen. Von Dr. Josef Zikowsky. Hautkrankheiten der Neugeborenen und Säuglinge. Von Priv. Doz. Dr. Gustav Riehl. Die generalisierten exfoliativen Erythrodermien. Von Prof. Dr. Alois M. Memmesheimer. Titel und Inhaltsverzeichnis zu Band III. Paper Price 16.50 marks. Pp 739 1062 with 112 illustrations. Berlin & Vienna Urban & Schwarzenberg 1934.

These volumes contain a number of complete, almost monographic, contributions by various authorities in the dermatologic domain. The subject of skin diseases caused by animal parasites is taken up by Grütz in a well illustrated chapter of 100 pages. The clinical and therapeutic problems in tuberculosis of the skin are exceedingly well presented by Hämel and Hoede from material in Zieler's clinic in Würzburg. The illustrations in this chapter are excellent photographic reproductions and present the varied anatomic features of cutaneous tuberculosis in great detail. There is a sane discussion on the treatment of lupus in which there is an evaluation of all the more modern therapeutic procedures. Other contributions that deserve particular commendation are those of Volk on diseases of the sweat and sebaceous glands. Stein's chapter on diseases of the hair, and Kren's chapter on disorders of the oral mucous membranes.

**Spinal Anesthesia. Technique and Clinical Application.** By George Rudolph Myers M.D. Cloth Price \$4.50. Pp 269 with 81 illustrations. St. Louis C. V. Mosby Company 1934.

Spinal anesthesia is discussed from the standpoint of its physiologic effects on the vital organs and on the body as a whole with frequent reference to the distribution of nerves, the effect of the anesthetic on them and the resulting phenomena. The author features his investigations and previous papers on this subject. The book is well illustrated. Little new material of importance is included. Those enthusiastic over spinal anesthesia will be interested in this book.

**Nachbehandlung nach chirurgischen Eingriffen.** Von Prof. Dr. Eduard Melehor. Primärarzt der chirurgischen Abteilung des Stadtischen Wenzel Hancke Krankenhauses Breslau. Second edition. Paper Price 17.60 marks. Pp 376 with 28 illustrations. Leipzig Johann Ambrosius Barth 1934.

The author reports his experiences in postoperative treatment, taking up each condition in detail. The discussion is arranged systematically under respiratory diseases, heart collapse, shock, vomiting, ileus, diarrhea, genito-urinary disturbances, infections, thrombosis, embolism, postoperative psychosis and various other complications of postoperative recovery. A number of other conditions, as blood transfusion and the care of diabetic or other systemic diseases during recovery, are included. Complications are then taken up following surgery of the special regions of the body, including that of the head and neck, thorax, abdomen and extremities, and discussed from this point of view. Numerous suggestions are made for the prevention and treatment of most of the undesirable complications following operation. Other suggestions are made for the comfort of the patient. The thoroughness and the detail make the book highly valuable as a reference work in the postoperative care of surgical patients.

**The Negro Professional Man and the Community with Special Emphasis on the Physician and the Lawyer.** By Carter Godwin Woodson. Cloth Price \$3.25. Pp 365. Washington D. C. Association for the Study of Negro Life and History Inc. 1934.

This volume is one of a series dealing with various phases of Negro life in America. Figures are presented showing the number and distribution of various professional and semiprofessional classes. These statistics are supplemented by the conclusions drawn by five investigators who traveled through the South and those Northern cities having a considerable Negro population. Questionnaires and interviews were reported from 1051 physicians, 656 dentists, 625 nurses, 388 pharmacists and 503 lawyers. Although teachers and preachers greatly outnumber the professions here named, their status is so much more generally understood that the author concerns himself with them only to the extent of their relationship to others. An attempt is made to analyze the factors that determine the Negro's choice of a career, his selection of a location, and the value of his service to the community. On such a broad theme the conditions found are necessarily indefinite. There are figures a plenty, but the meaning of the figures is not revealed.

**Narkose zu operativen Zwecken.** Von Dr. Hans Killian Oberarzt Chirurgischen Universitäts Klinik Freiburg i. Br. Paper Price 24 marks. Pp 406 with 165 illustrations. Berlin Julius Springer 1934.

This book, as the author says in the foreword, was written to afford a work on modern general anesthesia giving the German ideas and point of view and is the result of many years of experimental and clinical work. The first chapter is an outline of the history of anesthesia. The action of the general anesthetics on the blood, the temperature, the urinary tract the liver and metabolism, the brain, the skin and mucous membranes, the skeletal muscle, the intestinal tract and the uterus is discussed. In the chapter on the technic of general anesthesia the author mentions the preanesthesia examination of the patient. The signs of the depth of anesthesia and the complications of anesthesia are given in detail. In the chapter on statistics there is a discussion of the causes of death in the various stages of anesthesia and afterward, and there are tables showing lung complications after general and after local anesthesia by several different workers. Another table shows the average mortality of the different general anesthetic agents. There is a chapter dealing with the sensitivity of the patient and the indications for general anesthesia. The author states that the indications for anesthesia and those for operations have the closest relationship because the nature, dosage and duration of the former are directly dependent on the demands of the latter. The development of local anesthesia has taken more than half the work from the field of general anesthesia. The last chapter deals with special technical methods in the administration of general anesthetics, including nasal insufflation, intrapharyngeal, intratracheal, high and low pressure apparatus, carbon dioxide absorption, and portable machines. A discussion of the dangers of explosion (especially of ethylene and acetylene) closes the work. This book should be of considerable interest to anesthetists.

## Medicolegal

**Multiple Neuritis Attributed to Chronic Sulphuric Acid Poisoning**—The deceased had been for many years employed by the defendants in a bleachery, where cloth was being finished by passing it through a 2 per cent solution of sulphuric acid. To keep this solution at a uniform strength, the deceased tested it from nine to thirty-five times a day. Hydrometers were provided for that purpose but, during the whole period of his employment, employees customarily tested by tasting, and that practice was well known to the defendant. Following that practice, the deceased would dip his fingers into the solution and apply them to his tongue. He died from multiple neuritis. Attributing his disease and death to the practice, his administratrix sued his employers. Verdicts were rendered in their favor, and the plaintiff appealed to the Supreme Court of New Hampshire.

It has been known to the medical profession for many years, said the Supreme Court, that sulphuric acid is injurious if taken internally in small quantities over an extended period of time. The defendants were chargeable with knowledge of that fact. Being chargeable with that knowledge, the evidence warranted a finding that the defendants were negligent in permitting a dangerous method of testing the acid solution without warning to their employees of the danger. The furnishing of hydrometers would not protect the defendants' employees unless proper instructions as to their use were given and enforced, or unless appropriate warnings as to the danger of adopting alternative methods of testing acid solutions were given. The defendants contended that their overseer on several occasions directed or requested the deceased to use the hydrometer, in order 'to turn out better work' but even if this were so, the evidence would clearly justify a finding that the defendants had acquiesced in the habitual disregard of the overseer's instructions so that they had become a dead letter.

Evidence was offered to show that the deceased had had two attacks of influenza, which would render him more susceptible to injury by the sulphuric acid, and the court instructed the jury that if the deceased would not have developed multiple neuritis, had he not previously had an infectious disease, the defendants were not liable. This instruction the Supreme Court held to be erroneous. The jury might have found that the fatal disease was caused by the combined effects of sulphuric acid poisoning and the grip or influenza infection. The defendants would not be relieved from the natural consequences of their wrong, merely because other factors contributed to bring about the injury.

A new trial was ordered—*Musgrave v Great Falls Mfg Co (N H)*, 169 A 583.

**Malpractice Admissibility of Evidence Concerning Medical Defense Activities of State Medical Society**—In this third trial of this malpractice action<sup>1</sup> the defendant-physician, a member of the state medical society, called an officer of the society to testify on his behalf as a medical expert. On cross-examination, the witness testified that he paid dues to the society and that part of the dues so paid was allocated to a fund used to defend malpractice actions against members of the society. On redirect examination, he testified that the society did not defend every member and that the medicolegal committee of the society decided which members should be defended. He was then asked to tell which members the society defended, but the court refused to permit him to answer, holding that the question was an attempt to substitute the judgment of the medicolegal committee for the judgment of the jury. Judgment was given in favor of the plaintiff-patient, and the defendant-physician appealed to the Supreme Court of Michigan. He apparently urged as error the refusal of the trial court to permit the witness to state which members of the society were given the benefit of the society's aid, when sued for alleged malpractice. The testimony elicited from the witness on cross-examination, said the Supreme Court

as to his payment of dues and the use of such dues, was competent as bearing on the interest and credibility of the witness. The trial court erred, however, in refusing to permit the witness to state his understanding of the society's practice in defending malpractice suits. The witness's understanding of the practice was relevant to the claim of his interest and should have been received. The record, however, said the court, does not demonstrate that the erroneous ruling was prejudicial to the defendant. The judgment in favor of the plaintiff was, accordingly, affirmed—*De Haan v Winter (Mich)*, 251 N W 391.

**Right of Optical Corporation to Provide Licensed Optometrists for Customers**—The Kindy Optical Company was incorporated to "carry on the business of optician and dealer in optical goods and allied lines." It employed licensed optometrists to serve customers in connection with sales of optical goods. Through quo warranto proceedings the state sought to oust it from employing such optometrists for the purpose named. The state claimed that the company's articles of association did not authorize the company to render such service and that the law prohibited a corporation from operating an optometric department. From an adverse judgment in the circuit court, Wayne County, the state appealed to the Supreme Court of Michigan. The employment of an optometrist in connection with the sale of optical goods by the defendant, said the Supreme Court, is a natural and proper extension of the service it is authorized to perform. The optometry practice act of Michigan<sup>1</sup> contemplates the maintenance of optical departments by corporations in connection with the sale of optical goods. Many decisions which have been cited construing different statutes are not applicable to the construction of the Michigan act. The judgment in favor of the defendant optical company was affirmed—*Voorhees, Attorney General v Kindy Optical Co (Mich)*, 251 N W 343.

## Current Medical Literature

### AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (\*) are abstracted below.

**Changes in Tuberculous Cavities Resulting from Paralysis of Diaphragm**—Slavin observed that therapeutic paralysis of the diaphragm produces obliterative changes in pulmonary tuberculous cavities partly through compression but mainly through concentric retraction of the relaxed capsule of the cavity. Only those cavities the walls of which are compressible and capable of fibrotic retraction are influenced by interruption of the phrenic nerve. Complete closure of responsive cavities depends on their size and on the condition of the opposite lung and is not controlled by the amount of elevation of the paralyzed diaphragm. Cavities situated in the lower lobe show more initial compression and obliterate more rapidly than cavities of the upper lobe. As an aid in the closure of pulmonary tuberculous cavities phrenic paralysis presents the least radical procedure, and its application in selected cases saves the patient the inconvenience of prolonged pneumothorax treatment, the risk of major surgical collapse operations and the uncertainty of protracted expectant therapy.

**Desensitization of Guinea-Pigs by Means of Natural Tuberculin**—Weinzirl and Weiser state that tuberculous guinea pigs can be desensitized by means of a natural tuberculin prepared from tubercle bacilli subjected to repeated freezings with liquid air. No desensitizing powers could be demonstrated from the cell debris remaining after the removal of the natural tuberculin. The natural tuberculin successfully desensitized guinea pigs infected with either nonvirulent or virulent tubercle bacilli. Desensitization was effective against both Seibert's synthetic medium tuberculin and the homologous natural tuberculin.

**Tryptophan Test in Tuberculous Meningitis**—Rosenblatt used the tryptophan test in twelve cases of tuberculous meningitis proved by necropsy or by demonstration of the tubercle bacillus in the spinal fluid. All these cases gave unquestionably positive reactions. The control group consisted of forty-five cases. The presence of a positive tryptophan test is strongly suggestive but not pathognomonic of tuberculous meningitis. Hemorrhagic purulent and xanthochromic fluids give false positive reactions which are usually distinguishable from those obtained in tuberculous meningitis by the purplish color. Indistinguishable positive reactions may be obtained with clear spinal fluids in which the protein is increased. There is sufficient evidence to warrant the use of

the tryptophan test as a routine procedure in the examination of the spinal fluid.

**Red Cell Sedimentation Rate in Tuberculosis**—Siltzbach studied the erythrocyte sedimentation reaction curves (Cutler) in 494 patients having pulmonary tuberculosis. 1,170 individual tests were performed. The data so obtained were analyzed, and correlative studies with the constitutional and local manifestations of the disease were made. It was found that curves reflecting moderate and severe activity occur with greater frequency in patients with fever, rapid pulse, loss of weight, positive sputum, the formation of cavities, extensive lesions and extrapulmonary tuberculosis. The erythrocyte sedimentation reaction curve reflects the progress of the disease and a change in the erythrocyte sedimentation reaction curve often precedes the change in clinical symptoms and signs. It is of value therefore, in the prognosis of pulmonary tuberculosis. In collapse therapy the erythrocyte sedimentation reaction may be utilized as a gauge of the effectiveness of the treatment.

**Multiplane Chest Electrocardiography**—Weinstein proposes a standardized method of chest lead application which surrounds and intersects the heart by planes of current take-off, and he presents the uniformity of the tracings obtained in a control group of fifty normal cases and the advantage of the multiplane chest leads in conjunction with the three standard limb leads in more accurately detecting and localizing myocardial lesions. The right and left arm electrodes are used for the chest application and they are so placed that the current take-off is kept in the same relationship to the current direction within the heart as in the three standard limb leads. The right arm electrode is therefore always applied to the chest in closest relation to the tail of the arrow, while the left arm electrode is applied in closest relation to the head of the arrow representing the heart action current direction. It is important to determine accurately the size of the heart and the position of the cardiac borders either by a teleroentgenogram, fluoroscopic methods or by as accurate percussion as is possible. Flexible electrodes, one-half inch wide and from 4 to 6 or more inches in length, depending on the size of the heart, are used. The electrodes should be covered with gauze soaked in warm sodium chloride solution. The skin at the sites selected is cleansed with an antiseptic solution, and linear scarifications, the length of the electrodes used are made. The electrodes are held firmly in place either by an assistant whose hands are insulated with rubber gloves or, preferably, by a spring clamp device. The skin resistance should be carefully standardized before each lead is taken. The author presents illustrations of the positions of the electrodes on the wall of the chest.

**Malaria Therapy in Asymptomatic Neurosyphilis**—In the past ten years O Leary treated with malaria eighty-nine patients who had asymptomatic neurosyphilis when the serologic tests on the spinal fluid had failed to become reversed to negative following intensive use of arsphenamine and mercury and bismuth compounds. In 50 per cent of the cases in which invasion of the nervous system was of mild degree the serologic reactions became completely negative following malarial therapy,

irrespective of whether or not antisyphilitic treatment was given after induction of malaria. In 39 per cent of cases in which the formula of the spinal fluid was of the paretic type, the spinal fluid factors were reversed to negative following malarial therapy. Among those cases in which the usual antisyphilitic treatment was not given following malarial treatment, there was satisfactory reversal to negative of the spinal fluids in 58 per cent of those in which reports on the spinal fluid had indicated only mild or moderate involvement, whereas among cases in which the formula of the spinal fluid was of paretic type, in only 30 per cent was there a reversal to negative. When it was observed that the results from malarial therapy alone were unsatisfactory at the end of the first year, arsphenamine and mercury or bismuth compounds again were given intensively. In other words, if favorable results from malarial treatment were lacking at the end of six or twelve months, intensive specific antisyphilitic measures were instituted in an effort to ward off the appearance of parenchymatous changes in the nervous system. The absence of serologic relapse was noteworthy. In only one case did the author find a relapse to positivity of the spinal fluid after a negative report had been obtained following malarial treatment. Death occurred in one case, the cause for which could not be found at necropsy. He believes that there is ample evidence to allow the assertion that asymptomatic neurosyphilis is the forerunner of dementia paralytica or tabes dorsalis. Also, it is an acknowledged fact that in many cases of asymptomatic neurosyphilis a satisfactory serologic response follows intensive application of the so called specific remedies. Those patients who fail to derive serologic reversal from specific agents are entitled to the benefit of malarial therapy because, on a basis of comparative percentages, malarial therapy is more valuable in the prevention of parenchymatous neurosyphilis than it is in the treatment of it.

**Calcium Ortho-Iodoxybenzoate in Treatment of Arthritis**—Wheeldon observed the effect of calcium ortho-iodoxybenzoate in a general group of 236 arthritic cases and presents a detailed study of forty-six cases of hypertrophic and atrophic arthritis. The therapeutic results were most satisfactory and unpleasant side reactions were almost nonexistent. Laboratory observations indicate an increase in indican output, improvement in hypertension and lowering of sedimentation rate. The author is of the opinion that calcium ortho-iodoxybenzoate achieves its beneficial results through its stimulating action on the peripheral circulation and that, subjectively at least, calcium ortho-iodoxybenzoate improves the circulation in the affected joints.

**Electrocautery in Treatment of Laryngeal Tuberculosis**—Vandever states that laryngeal tuberculosis is a complication of pulmonary tuberculosis in practically every case. The tuberculous lesion is healed by the deposit of calcium salts in the necrotic areas and by the increase of fibrous tissue which develops from the fixed connective tissue cells, and probably by a changing of the epithelioid cells into fibroblasts. Such healing processes are encouraged by an increased blood supply. Rest is important in all cases of laryngeal tuberculosis. The

electric cautery is used in all tuberculous ulcers and infiltrations, that do not respond to rest. The electric cautery heals, not by the destruction of all tuberculous tissue, but by the development of an inflammatory zone in which newly formed blood vessels and fibroblasts are produced, which hastens healing by cicatrization. Most early cases heal with cautery treatment, while there is relief from pain in the advanced cases. Electric cauterization is carried out best under cocaine anesthesia and by the indirect method.

**Treatment for Eustachian Tube Obstruction**—Simon uses heat bougies in treating eustachian tube obstruction. He varies the procedure at different times, but essentially it is the insertion of the bougie through a short (Yankauer) catheter and then turning on of the heat gradually at the rheostat dial until the galvanometer of the thermocouple reads 110 F. This temperature is maintained for a period of ten minutes, following which the heat is completely turned off but the bougie is still left in the tube. After ten minutes the bougie is withdrawn. The procedure was usually done weekly.

\*Repair of Coloboma of the Upper Eyelid L. A. Peer, Newark N. J.—p. 1028

**Treatment of Detachment of the Retina**—With special short needle electrodes, Safar makes multiple perforating diathermic punctures in the area of the bulbar wall where the rent of the retina is situated or is supposed to be. After the subretinal liquid has escaped through these punctures, the retina attaches to the coagulated choroid and becomes adherent to it, the tear disappears, and the detachment of the retina heals. Since this method can be applied over a large area with slight intensity of current, it is applicable in cases of large tears or multiple holes as well as in those without visible tears. The location of the tears is considerably facilitated by scattering the punctures. The method is simple and efficacious, and the burden on the eye is minor, particularly if the condition is recent, patients presenting such a condition may be operated on with nearly absolute certainty of success. Complications are rare. In the author's cases reattachment of the retina has been permanent to the present time in 57.5 per cent of forty eyes operated on without selection in 1932 and in 85 per cent of the first forty eyes operated on in 1933. Failures occurred in cases of old detachment, with a shrunken or contracted retina due to an operative scar, and in old people who could not be kept in bed in the prone position for a sufficient length of time and who were inclined to bleed; however, hemorrhages into the vitreous are rarer with this method than with other methods. Retinas with older detachments, with the formation of striae and a boundary area, could still be reattached. Sometimes there was a surprising improvement in visual function. Generally, however, early operation is indicated, for the longer the detachment persists, the less is the chance for reattachment and the regaining of useful function of the retina.

**Repair of Coloboma of Upper Eyelid**—Peer reports a case in which coloboma followed the removal of a portion of the upper eyelid for basal cell carcinoma. The growth involved both the conjunctiva and the skin and was removed by excising a full thickness section of the lid extending from the free margin to a little above the upper border of the tarsus. A flap of skin from the eyelid was outlined above the defect, dissected from

the muscle layer and turned down trapdoor fashion, sufficient lunge or pedicle being left to insure an adequate supply of blood. This flap was sutured to the denuded edges of the defect with the surface of the skin next to the eye and the raw surface outside, and was left in place for one week. A free, full thickness skin graft was then taken from the opposite upper eyelid and sutured to cover the entire denuded area, only moderate pressure being applied to avoid strangulation of the skin flap. One week later the dressing was removed and artificial adhesions were made between the new portion of the upper and lower lids. The adhesions were left in place for four months and then severed. A notching of the margin of the lid due to imperfect union was repaired at this time by a procedure similar to the Blair-Mirault operation for harelip. The author has used this operation on other cleft lids and recommends it as a practical and satisfactory method.

**Attempts at Experimental Reproduction of Hodgkin's Disease.**—Steiner investigated the diseased splenic and lymph node tissues from fifteen patients having Hodgkin's disease (lymphogranulomatosis) together with control diseased tissues from eight patients with other lymphomas (1) for the ability of the diseased tissue to produce tuberculosis in chickens, guinea-pigs, rabbits, dogs and mice (2) for the disease-producing capacity of these tissues as grafts and (3) for the presence of tubercle bacilli or atypical acid-fast bacteria in these tissues, special cultural methods being used. The diseased tissues from the twenty-three patients were injected or transplanted into 199 animals. An additional group of twenty-three chickens that were not given injections served as a control of environmental factors, especially of the occurrence of spontaneous tuberculosis. A group of eight dogs received intracerebral injections. The animals were allowed to survive for periods varying from nine to thirteen months. In the entire group of animals given injections of diseased human tissues, tuberculosis occurred in one chicken and in one guinea pig following injection of material from a patient having Hodgkin's disease, and in one guinea-pig following injections of lymphosarcomatous tissue. In the infected chicken a spontaneous infection was not ruled out. In passage experiments with tissues from these infected animals, tuberculosis was again produced. Numerous lesions in diseased chickens superficially suggesting tuberculosis were considered nontuberculous because they did not definitely satisfy any of the following criteria: the acquisition of a positive reaction to tuberculin; the gross and microscopic morphologic structure of tuberculous lesions; the presence of stainable acid-fast bacilli in suggestive lesions; the growth of acid-fast bacilli from such lesions on culture mediums; and the production of tuberculosis in animals in passage experiments. No evidence was found that the diseased human tissues were transplantable or that they were capable of inducing in animals lesions with a similar histologic structure. No strains of acid fast bacteria were grown from these diseased human tissues by modern cultural methods. Likewise the occurrence of acid-fast forms of bacteria reported to exist as a transient phenomenon early in the cultures of these tissues was not confirmed. Avian tubercle bacilli detectable by the methods used were apparently not present in the tissues of the fifteen patients having Hodgkin's disease.

**Metamorphosis of *Metastrongylus* Larvae and Mesenteric Lymph Glands.**—The study of Hobmaier corroborates the previous statement of A. Hobmaier and the author that the infective larvae of *Metastrongylus* must invade the mesenteric lymph nodes of the vertebrate host to grow there into sexual larvae and that they do not enter the tributaries of the portal vein as a part of their regular life cycle. The patho-

logic changes observed in the invaded lymph nodes may be explained as the result of the trauma inflicted by the embolization of the larvae into the lymphatics, by the dilatation and occlusion of these vessels during the development of sexual larvae, and by the disarrangement of anatomic structures caused by their emigration.

**Composition of Lymph in Formation of Edema.**—The experiments of Weech and his associates indicate that lymph flow in normal dogs ceases entirely during periods of complete physical inactivity. During these periods, capillary filtrate accumulates in the interstitial spaces and can enter the lymph channels at once when activity stimulates the pumping action of the lymphatic valves. The initial flow is therefore rapid, but the rate declines quickly as the interstitial reservoir is emptied and finally becomes constant at a rate which corresponds to that at which new lymph is being produced. With

the edematous dog the situation is similar, but because the interstitial spaces contain more fluid (edema) the initial rapid flow can be maintained for a longer time than in the normal animal. Within ten or fifteen minutes, however, the rate of flow decreases and continued activity is accompanied by progressive and finally by complete loss of edema. The carrying capacity of the lymph vessels at all times greatly exceeds the rate at which new lymph can be formed. The data suggest that the rate of lymph formation, as estimated from the minimal rates of lymph flow, may increase slightly when edema is present. The increase, however, is surprisingly small and not beyond the limits of variations encountered in normal animals. Lymph from the normal dog always contains an appreciable quantity of protein. Lymph from the edematous dog contains much less protein. The lymph protein deficit of edematous dogs is greater than can be accounted for on the basis of a proportionate loss corresponding to the serum protein deficit. The concentration of protein in lymph from edematous dogs is of the same order of magnitude as that of edema fluids, although the two fluids are not identical in composition. Minor fluctuations in the protein of lymph occur while the collections are being made. The fluctuations may depend on varying proportionate rates of flow from different regions that send tributaries to the main lymph channels or they may result from variations in capillary permeability incident to the continuous exercise necessary for maintaining lymph flow. Lymph from the lower leg of normal and edematous dogs sometimes contains red blood cells and sometimes it does not. Both increases and decreases in the number of erythrocytes may follow in succession as the conditions of collection are altered.

**Sedimentation Reaction in the New-Born**—The results of Ellenberg's investigation show that the sedimentation time in the normal new-born infant seems to range between seven

and twenty-three hours, with the average sedimentation speed for the entire neonatal period being about fifteen hours as compared to the two hours considered normal in adults. There is also a tendency for the sedimentation reaction to become less prolonged as the infant grows older. Silzer, in a study of the sedimentation speed of red blood cells from the umbilical vein of 800 infants, noted that 91.75 per cent of the cases showed a sedimentation time of more than twenty-four hours, 4.25 per cent showed sedimentation in from twelve to twenty-four hours, 3.8 per cent in from one to twelve hours, and 0.5 per cent in from thirty to sixty minutes. That the blood fibrinogen is probably the most important factor in the prolongation of the sedimentation reaction in infants is suggested by the work of Bruchsalter, who studied the relative sedimentation reaction and blood fibrinogen in infants and pregnant women and found that the maternal blood showed from 250 to 500 units of fibrinogen, while the blood of new-born infants contained from 64 to 125 units. The author discusses the use of the superior longitudinal sinus as a source of obtaining blood for the study of the sedimentation speed in the new-born infant.

**Vascular Response to Drainage of Ascites**—Brams and Golden noted the effect of draining off abdominal fluid on the venous pressure, systolic and diastolic arterial blood pressure and pulse rate in ten patients having portal cirrhosis and chronic ascites. The venous pressure began to fall early during the drainage, and in four instances continued as more fluid was removed. The venous pressure at the end of the drainage was lower in every instance than before tapping was begun. Systolic and diastolic arterial pressures fell while the fluid was being removed. A fall in blood pressure was associated with faintness in one patient, whose pressure was low before the procedure was begun. A similar fall in other patients with previously normal blood pressure was not associated with such untoward symptoms.

**Chemotherapeutic Studies with Sodium Ricinoleate**—Kolmer determined the toxicity of sodium ricinoleate by intravenous, intraperitoneal, intramuscular and subcutaneous injection in the lower animals. It is highly hemolytic and on intravenous injection may produce intravascular hemolysis with embolism. The maximal tolerated dose by this route of administration has been found to be approximately 0.035 Gm per kilogram of weight. By intramuscular injection it may produce local irritation, with liquefaction necrosis when large amounts are injected. However, it is well borne systematically by this route of administration, as the maximal tolerated dose has been found to be more than 1 Gm per kilogram of weight. It may also produce some irritation on intraperitoneal injection but it is well borne by this route, since the maximal tolerated dose is as high as from 0.16 to 0.3 Gm. per kilogram of weight. By intracisternal injection the maximal tolerated dose has been found to be approximately 0.004 Gm per kilogram of weight. Sodium ricinoleate is capable of inactivating or destroying diphtheria and tetanus toxins in the test tube and is especially destructive for the latter, although it would appear that the resulting toxoids are of low antigenic activity. It is but feebly antitoxic for the toxins of diphtheria and tetanus bacilli in guinea-pigs by various routes of administration. Sodium ricinoleate is of low bactericidal activity in the test tube and has been found without demonstrable curative activity in severe streptococcal, pneumococcal and tuberculous infections of the lower animals, as well as in experimental trypanosomiasis of rats, syphilis of rabbits and acute anterior poliomyelitis of monkeys.

**Modification of the Colloidal Gold Test**—Boerner and Lukens recommend the following modification of the colloidal gold test, which requires but one-half the amount of reagent that is used in the original method. Eleven chemically clean test tubes are placed in a rack. Into the first tube 18 cc of a 0.4 per cent solution of sodium chloride is placed, and 0.5 cc in each of the remaining ten tubes. To the first tube 0.2 cc of spinal fluid is added and mixed thoroughly. The authors feel that the dilutions will be more accurate if 0.2 cc. of fluid is diluted with 18 cc of salt solution rather than 0.1 cc. of fluid with 0.9 cc of salt solution. If the latter is used, the 1 cc is not discarded from the first tube as directed in the next step. From the first tube 1 cc is discarded, then 0.5 cc

is transferred to tube 2, mixed thoroughly and 0.5 cc removed and placed in tube 3, this is continued until the tenth tube is reached and then 0.5 cc is discarded from this tube. The eleventh tube is used as a control. To each tube 25 cc of colloidal gold solution is added, mixed thoroughly and set aside for twenty-four hours. The readings are made and recorded as in the original test.

**Atypical Chondrodystrophy**—Warkany and Mitchell describe a case that presented certain features of chondrodystrophy but, as others were lacking, it was difficult to decide between this diagnosis and that of osseous dystrophy. In reality, the case represented an intermediate form between the two diseases. In common with Morquio's disease, it had normal skull and conformation of the face, lack of micromelia, lack of development of the epiphysis of the head of the femur, genu valgum, normal length of the fibula, waddling gait and some faulty development of the musculature. The apparent late onset of symptoms also speaks for Morquio's syndrome. The case resembled Parrot's type of chondrodystrophy in that the neck and trunk were of normal length, there was no platyspondylitis, and the humeri were short and thick.

**Effect of Extract of Pregnancy Urine on Hypopituitarism**—Kunstader and Robins treated eight male children having hypopituitarism with extract of pregnancy urine (antuitrin-S). Descent of the testicles was accomplished in all of three cases of cryptorchism. In three cases characterized by genital underdevelopment (testicles descended), treatment resulted in enlargement of the testicles and scrotum and the appearance of the secondary sex characteristics. In two cases characterized by pituitary obesity with normal genital development, treatment resulted in no increase in size of the genitalia. In four of five cases in which basal metabolism tests were made before and at the end of treatment, the basal metabolic rates were lowered below the lower limits of normal at the end of treatment. The inconsistency of the change in blood cholesterol level following treatment does not permit definite conclusions. In five cases in which sugar tolerance determinations were made before and at the end of treatment, the tolerance was lowered at the end of treatment. In seven of the eight cases there was an increase in growth of stature above the normal for the age following treatment. The extract of pregnancy urine did not stimulate loss of weight and did not alter the typical pituitary distribution of fat.

**Pharmacology and Toxicology of Pyridium Hydrochloride**—Walton and Lawson observed that intravenous injections of pyridium hydrochloride in relatively large quan-

ties (from 25 to 100 mg per kilogram of weight) are well borne by laboratory animals. Gross cardiac irregularities are absent, as well as any pronounced effects on the coagulability of the blood. The sudden fall in blood pressure caused by the injection of the hydrochloride is transitory and is produced only by large doses injected rapidly. The hydrochloride is more toxic than the free base when injected intraperitoneally in rats. No marked toxicity is developed by the free base on standing open in solution. With fatal dosages there is no pronounced cyanosis or massive methemoglobin formation, as is the case with aniline, acetanilid and other so-called blood poisons. As judged by the emetic effects in dogs, the gastric irritation of the free base and of the hydrochloride is closely similar. Measurable amounts of methemoglobin, as determined by the Stadie-Van Slyke method, can be produced on oral administration of this drug. However, the relatively large dosage required indicates that this is not a complication to be expected in the usual clinical administration. Formation of methemoglobin by large overdoses is usually accompanied by a decrease in total pigment. This effect is probably closely related to the anemia produced in chronically treated animals. The most marked effects obtained by prolonged administration are liver degeneration and erythrocyte destruction. Since three dogs received an average of one and a half times the therapeutic dose for from forty-two to sixty-six days and suffered only moderate to slight effects on red cell counts, liver and kidney structures and general condition, the authors believe that this drug should not be dangerous if administered over short periods in the usual therapeutic dose of 10 mg per kilogram. Prolonged administration involves possibilities of damage.

**Blood Transfusions in Treatment of Septicemia in Children**—Roehm and Barker used whole, unmodified blood transfusions in six cases of septicemia in children, five recovered. The one death occurred thirty-six hours after admittance to the hospital and was the only case of hemolytic streptococcal infection in the series. One case was due to *Staphylococcus albus*, three to nonhemolytic streptococcus and one to an infection with a nonhemolytic streptococcus and an unidentified diphtheroid organism. Two of the six cases presented a generalized peritonitis demonstrated by abdominal paracentesis and examination of the abdominal fluid both directly and by culture. The sole treatment in the six cases was transfusion of whole unmodified blood, except for supportive measures and operation in the one case of osteomyelitis. The author includes a case of peritonitis due to a ruptured appendix for a comparison of the observations in the peritoneal fluid in this type of peritonitis with that of peritonitis due to septicemia.

**Denervation of the Ureter for Renal Colic**—Hepburn points out that intractable renal colic in cases in which no obstructive cause can be found may be due to spastic obstruction of the ureter. Denervation and lateral displacement of the ureter is a logical surgical procedure in such a condition. He presents another clinical case to support this contention. The claim is made that denervation is more completely done from the retroperitoneal approach and that the added factor of lateral displacement makes less probable the regeneration of the spastic nervous mechanism and relieves any redundancy that may have developed in the ureter thereby improving drainage of the renal pelvis and relief from pyelitis. While it is recognized that spastic ureteral obstruction is doubtless a common cause of renal colic in both sexes, the extreme spasms that require denervation are quite rare, and in all reported cases they have been found in women. Wharton's anatomic dissections revealing a connection between the sympathetic nerve supply of the ovary, testicle and ureter would seem to give a sound neurologic mechanism to substantiate the hypothesis of a probable sexual foundation for these severe spasms. That they occur more frequently in women than men is because sexual emotional defeat occurs more often in women than in men.

**Technic for Placing Artificial Ligaments at the Knee**—Cotton and Morrison describe a technic of placing artificial ligaments at the knee for ruptures of the lateral ligaments or crucials, the principle of which is the X suture placed deeply and the use of a fascial band. The essential thing about it all is that, with one or both laterals gone, satisfactory ligaments may be constructed out of fascia. To avoid interference with motion the resultant ligament must be attached near the radial center of the curve of the femoral joint surface, seen laterally just below the tip of the adductor tubercle, in making an internal lateral ligament and not too far back or front at the tibial attachment. To get strong bony mooring the fascial strip must go under a strong bridge of bone rather deep into the cancellous bone. That means two holes and, in order to avoid an undesirable broad ribbon of ligament, it means an X crossing of the false ligament. The fascia is drawn taut and knotted and the knot is fastened with gut or fine silk sutures. The whole operation, even if both inner and outer sides are operated on, can be done without opening the knee joint. Motion is begun at three weeks and weight bearing at six weeks, then a convalescent splint is used, as there is a slacking up of the ligament. This slack "takes up" with time but is likely to persist for four months or more.

**Treatment of Erythroblastosis of the New Born**—As soon as a case of erythroblastosis is suspected, Arnold and Downey take a hemoglobin, blood smear, and cross agglutinate. As soon as the diagnosis is made and the hemoglobin drops from 100 to 125 cc of compatible blood is given intravenously by cutting down on the internal saphenous vein at the internal malleolus or half way up the leg parallel and just to the medial side of the tibial border. The transfusion is repeated daily or every other day as indicated, depending on the general condition of the patient and the hemoglobin estimation. If a condition of insufficient fluid intake exists a slow intravenous drip can be instituted, and if the cannula remains patent it is often possible to retransfuse without having to open another vein. Transfusion replaces the hemolyzed blood with a functionally good blood and stops hemorrhage. The hemoglobin, which often drops as low as from 20 to 30 per cent, should be kept up to 70 or 80 per cent. Most cases require at least three and usually not more than four transfusions. The rest of the treatment is general hygiene with directions as to food, fluid intake being managed enterally or if necessary parenterally.

**Establishing Suprapubic Drainage**—When it is impossible to introduce an indwelling catheter through the urethra, Evans establishes suprapubic drainage in the following manner. The tissues are infiltrated with 0.5 per cent solution of procaine hydrochloride. The skin above the space of Retzius is incised for about one-sixth inch with a small knife. A straight trocar is thrust into the bladder, the trocar is removed, leaving the cannula in the bladder temporarily. A soft rubber catheter is inserted through the cannula, which is in the bladder, gently pushing the catheter well into the bladder. The cannula is gradually pulled out of the bladder, slipped over the rubber catheter, which has been cut off at the distal end. The tissues

fit snugly around the catheter, holding it firmly in place, but the catheter can be retained by a suture or a safety pin with adhesive tape.

More on X Ray Protection Standards A Mutscheller New York —p 739

Roentgen Treatment in Epidemic (Lethargic) Encephalitis—Goldberg and his associates say that in the treatment of epidemic encephalitis only minute doses of the roentgen ray are necessary. In the three cases that they report this method of treatment shortened the duration of the illness and the period of hospitalization. Because of the removal of the pressure before permanent damage was done to the nerve cells, the treatment certainly obviated the devastating postencephalitic effects. The authors are now attempting to treat cases in which there has been a postencephalitic syndrome of long duration. While they do not expect any beneficial results, on account of permanent damage already done they feel that this treatment should be given a trial.

Cardiac Measurement of the Frontal Silhouette—Rona and Herrman made a study of 126 healthy and ninety-four pathologic hearts and present a new method of mensuration in the frontal plane. The method demonstrates the enlargement of either or both ventricles and differentiates between inflow and outflow tract changes on the frontal plane without the making of additional films. The method shows a reliable correlation of the various diameters to one another and to the size of the heart. It makes the cumbersome and unreliable frontal area measurement superfluous and supplements it with figures at which it is easy to arrive. The range and the mean average of the diameters showed a characteristic change in, and according to, the pathologic condition of the ventricles. Normally the left ventricle is the longest diameter but, if the right ventricle is longer, a pathologic condition should be looked for. Normally the right auricle is longer than the left. Pathologic conditions tend to enlarge the left auricle. A pathologic change in the right ventricle (inflow tract) goes together with a pathologic change in the left auricle (outflow tract).

Volvulus During Convalescence Following Perineal Prostatectomy Report of Case B Halpert New Haven Conn —p 140

Pepsin Therapy of Gastric Ulcer—Glaessner is convinced that pepsin-hydrochloric acid stands in primary relation to gastric ulcer. He believes that the idea in employing pepsin therapy for the treatment of gastric ulcer is to introduce an organ therapy which derives its activity (1) as a substitution therapy and (2) as an antibody therapy. His experiments on animals show that under the influence of injections of neutral pepsin a rapid healing and return to normal occurs. When these experiments are transferred to mankind, the healing of all forms of ulcers is considerably hastened and when this could not be accomplished at all, the healing was stimulated. He has treated more than 1,000 cases in the most varied stages and can say that pepsin therapy, of all bloodless treatments, shows the best results. The technic of the injection consists in the administration of an absolutely neutral pepsin solution, intramuscularly or subcutaneously. The solution must be sterile but not boiled, is harmless, and should not cause pain or anaphylactic symptoms. This injection, which is albumin free, has been proved to answer the purpose and can be given in ascending and descending doses, so that one series of treatments consist of ten ampules increasing, ten stationary, and ten falling doses, all numbered and complete in themselves. Coincidental with the injections, an internal medication of bismuth preparation is given bismuth silicate, bismuth carbonate with magnesium citrate or powdered magnesium or chalk, bismuth-magnesia—which have the purpose of coating the gastric mucous membrane and decreasing the acidity. In addition to this, each patient before meals (five a day) receives oil in quantities of five times from 15 to 20 Gm daily. This medication has the purpose of influencing the acid secretion. Finally the patient receives a diet consisting of milk, pastries, cheese butter, eggs, finely ground meat, strained vegetables with butter, puddings, fish, sardines, tomatoes, scrambled eggs, omelet, honey, toast, mild hams, gelatin, fruit sauce and soups without meat extract. The diet should be sufficiently nourishing and given five times a day. The patient must lie down twice a day for two hours and the use of diathermy, mudpacks or a hot water bottle will be of great value. The treatment is carried out strictly for thirty days, then for two months with somewhat increased diet without injections, and repeated two or three times at intervals of six months.

**Derangements of the Knee Joint**—Henderson reviews the records of 605 patients operated on for derangement of the knee, in which 626 operations were performed. His operation consists of isolation of the patella and patellar tendon down to its insertion. An external incision is made along the external capsule, a little above the upper margin of the patella, and is carried down to the patellar tendon. The dissection of the patellar tendon is carried out further, and its insertion is lifted up along with a good sized flake of bone and transferred well to the inner side on the tibia and at a slightly lower level. The area to which it is transferred is thoroughly freshened, denuded and roughened. The end of the patellar tendon is held firmly over this area and a beef bone screw is inserted, locking it in position. The external capsule is overlapped, as in hernia, and chromic catgut sutures are used. The author believes that, if this technic is properly and accurately carried out and protection afforded long enough after operation, a cure is practically assured. Following operation, the knee is put at rest in a plaster-of-paris cast, extending from the groin to the ankle and is held in that position for at least three weeks before mobilization is started. Motion is begun gradually, right angle flexion not being permitted for at least three months. The operation alters the mechanism somewhat, and some patients complain of stiffness and of pain, but these gradually disappear. If the insertion of the patellar tendon is moved far enough inward and held there until it becomes firmly attached, dislocation of the patella is impossible.

**Gastric Lavage in the Treatment of Pyloric Obstruction**—Freeman and Brown found that daily aspiration of the contents of the stomach was necessary following pyloric obstruction in cats. They observed that the animals which were subjected to repeated emptying of the stomach survived considerably longer than untreated controls. Therefore in order to determine the factors responsible for the longer survival of the treated animals they fed healthy adult male or nonpregnant female cats that had fasted for twenty-four hours a mixed diet of meat and milk. Emptying the stomach and washing it out allowed the animals to live almost twice as long as those which accumulated their secretions until they vomited. In no case did a cat whose stomach was regularly

emptied die sooner than the control animal. The average daily loss of water and chloride per unit of body weight was decreased when gastric lavage was repeatedly performed. The diminished rate of chloride loss was associated with a higher level of chloride in the blood. While the average fall in the chloride level of five untreated cats was from 677 to 444 mg per hundred cubic centimeters in 34 days, in four treated cats the average fall was only from 686 to 527 mg per hundred cubic centimeters in 45 days. The body temperature during the period of dehydration after pyloric obstruction varied only within 25 degrees F, generally being slightly lower at the end of the experiment. Analyses of the nitrogen of the gastric contents revealed only small quantities of protein, 0.25 per cent in an average of five experiments. The nonprotein nitrogen content increased as the dehydration progressed. In one cat the concentration increased steadily from 74 mg on the first day after operation to 400 mg per hundred cubic centimeters on the fifth day. No correlation between the time of survival and the loss of nitrogen was found. The results obtained seem to indicate that the improvement in general condition after gastric lavage was due at least in part to a reduction in the rate of the loss of water and electrolytes from the body into the lumen of the stomach. The authors suggest that in clinical cases the benefit derived from gastric lavage is to be attributed in part to the decrease in the rate of the loss of chloride and fluid from the body into the stomach.

**Aspiration Biopsy**—Ball describes a method of needle biopsy in which the skin is prepared with iodine and alcohol and is anesthetized with a 1 per cent solution of procaine hydrochloride. A needle is slipped into the mass of the tumor, joint or bone, and a 50 cc luer syringe is connected. The plunger of the syringe is then pulled out as far as possible and grasped with the palm of the hand to hold the plunger and keep the vacuum. With the other hand the barrel of the syringe is rotated on the plunger with a slight withdrawal of the needle about 3 or 4 mm, and the needle is pushed back to its former position. The aspirated material is usually blood stained. After from 2 to 5 cc has been aspirated the needle is removed with continued traction on the plunger of the syringe. As soon as the needle is removed from the skin there will be a release of vacuum by the air rushing through the needle, which clears the needle of any fragments of tissue. The syringe is not to be emptied by closing the plunger. The plunger is removed and gauze is used to wipe out the syringe. The contents are spread on gauze moistened with sodium chloride solution and all bits of tissue are separated from the clot and piled together on a dry piece of paper and then dropped in fixing fluid. Sections are made in the usual manner, preferably by paraffin embedding. If it is desirable or indicated, primary smears and cultures may be made from the material before spreading it on the gauze.

**Sensitivity to Cow's Milk**—Tallerman tested the serums of eighteen infants in order to determine whether or not reagins were present in the blood of these children rendering them allergic to cow's milk. Eight of these infants gave completely positive results, while only two cases gave consistently negative results. Five gave results that were positive in one or more tests but equivocal in others. The remaining three gave contradictory results. Of the whole series of forty-two Prausnitz-Kustner reactions carried out, 61.9 per cent gave definitely positive results and only 19 per cent were definitely negative. It appears that reagins to cow's milk proteins are frequently present in the blood of infants suffering from gastro enteritis. From this one may conclude that many such infants are hypersensitive to cow's milk proteins. It is possible that some of the toxic symptoms of acute gastro enteritis may be in the nature of an allergic reaction.

**Aneurysm of Innominate Artery Treated by Proximal Ligation**—Souttar points out that ligation of the innominate artery for aneurysm is a well established surgical procedure in which the risks of the operation are entirely justifiable in view of the gravity of the condition. Technically the operation may be easy of achievement or the difficulties from adhesions may render it impossible. Apart from the risk of hemorrhage at the time of operation the two chief dangers to be feared are interference with the cerebral circulation and interference with the circulation in the arm. The latter does not appear to be as serious as might be imagined probably because during the existence of the aneurysm a wide collateral circulation has opened up. The danger to the brain however must always remain a serious one and there would seem to be no means of discovering the extent of the risk in any particular case. The author is convinced that the method adopted of operating under local anesthesia and of applying tentative ligatures to

the arteries, is a sound one. General anesthesia involves a disturbance to the circulation, which cannot be anything but inimical to the interests of the patient, while it precludes entirely the important information, which a conscious patient can give, as to the effects of occluding the circulation of a large vessel.

**Silicosis**—Gudjonsson and Jacobson describe a typical uncomplicated case of silicosis with fatal outcome in a porcelain turner. Microscopic examination of lung tissue and of ashes from it showed numerous mineral needles resembling those found in kaolin from the factory. The necropsy revealed no other condition that might have caused death. On the other hand, the changes in the lungs were so extensive and advanced that it is surprising that the man was able to go about with such lungs, as the lung tissue capable of respiratory function must have been reduced greatly in amount. The changes found in the heart were ascribed to the impaired circulation of the blood in the silicotic lungs—a condition involved in most cases of marked silicosis. It is certain that the dust this man inhaled for years contained much silicic acid. The observations in this case support in part the theory advanced by W. R. Jones, that silicosis can be produced by fibrous minerals.

**Varieties of Bacillus Paratyphosus B**—Warren and Iredale studied a series of nine cases of paratyphoid due to infection with anaerogenic strains of Bacillus paratyphosus B. Biologic examination of the strains shows no difference from the ordinary type of B. paratyphosus B except the inability to produce gas from any 'sugar'. Serologically the strains are identical with the aerogenic type of the organism. These anaerogenic strains retain their inability to produce gas from 'sugar' after subculture on artificial mediums for a considerable period, and cultivation on a number of different fluid mediums failed to restore the gas producing power. In the organic salt fermentation test B. paratyphosus B gives a characteristic reaction which is also given by the anaerogenic strains. The fermentative varieties of B. paratyphosus B defined by Kristensen and Bojen are definite and can be identified as a matter of practical routine, but the test is delicate and requires care in the preparation of the mediums and especially in the Bitter test. The existence of these apparently stable fermentative varieties of B. paratyphosus B is likely to be of use in epidemiologic investigations.

**Influence of Emulsions of Oils on Lethal Effects of Bacterial Toxins**—Myers states that olive oil emulsions, in

a fine state of division, when mixed with superlethal doses of diphtheria toxin, protect animals from the lethal effects of the toxin when injected subcutaneously. Olive oil emulsions also protect against the effects of superlethal doses of the toxins of *Clostridium tetani*, *Clostridium welchii* and *Clostridium oedematis-maligni* (Koch). The addition of a suitable emulsifying agent to give the emulsion greater stability makes the protection against the toxins absolutely secure. Emulsions of petrolatum have a similar protective action against lethal doses of these toxins, but the cream of cow's milk affords no protection. Coarse emulsions of these oils do not exhibit this protective action. The toxins of *Corynebacterium diphtheriae*, *Clostridium tetani*, *Clostridium welchii* and *Clostridium oedematis-maligni* are more soluble or have a greater affinity for water than oils. Solutions of acacia do not influence the lethal effects of these toxins. Diphtheria toxin when mixed with stable and finely divided emulsions of olive oil or petrolatum, before being injected subcutaneously, does not produce myocardial degeneration as observed in control animals.

\*Abscess of the Brain. H. W. MacKenzie—p. 357

Atrophic Rhinitis. J. Adam—p. 375

Notes on a Case of Suppuration in a Crista Galli Cell. C. M. Erdie—p. 397

**Abscess of Brain**—MacKenzie reports eight cases of brain abscess, six of which were cured. Seven of the cases were the result of chronic suppurative otitis media. Four of these were temporosphenoidal lobe abscesses, two of which were cured, and three were cerebellar abscesses, all of which were cured. In six of the eight cases drainage was done at operation and all the patients recovered. A decompression operation was performed in one of the remaining two cases, but before a final operation for drainage of the abscess could be carried out the abscess burst into the ventricle and the patient died. In the other, an exploratory operation was undertaken without success, but ultimately the abscess burst through the surgical wound and the patient died eight days later. In the treatment of a furuncle or an abscess incision before it is considered "ripe" delays healing, but, if operative intervention is postponed until local immunity has developed and a wall of inflammatory tissue has surrounded the pus, evacuation of the contents is followed by rapid cure. Just as too early incision will delay healing, so also will unnecessary delay be injurious. It is the author's procedure to postpone operation until pressure symptoms have become well marked, by which time a local immunity has been developed. Besides this development of immunity, delay renders the discovery and drainage of the abscess easy and also results in an immediate hernia of the brain on incision of the dura, which by compressing the dura against the bony margins of the trephine opening, lessens the risk of the onset of meningitis. In seven cases drainage was done through a clean trephine wound of from 1 to 1½ inches in diameter, situated either in the squamous portion of the temporal or posterior to the sigmoid sinus. In the eighth case of frontal lobe abscess, drainage was effected through the opening caused by an osteomyelitis of the frontal bone. The author's conclusions are that a "delayed" operation is necessary for success and that drainage through a large trephine wound is more likely to be successful than drainage through the mastoid alone. This allows the removal of the brain tissue sloughs, which, if retained, are liable to give rise to fresh abscess formation. The retention of tubes beyond forty-eight hours is unnecessary in most cases, for invariably by that time the hernia has forced them out, along with sloughs of brain tissue. In seeking for an abscess it is an advantage to use angular forceps, as the blades can be expanded and so allow the pus to escape.

### Specific Principle in Urine of Cancerous Patients—

The hypothesis that malignant tumors could be the source of some substance excreted in the urine served as the guiding point for the investigations of Aron. The first problem in this study consisted in the concentration of urine. Experience showed that the active principle was present in the precipitate formed by the addition of pure acetone or 95 per cent alcohol to the urine. It is impossible to say yet whether it is really precipitated or simply absorbed. The method employed was to add in a large flask a quantity of freshly passed urine to three times its volume of 95 per cent alcohol. After shaking a precipitate forms and settles slowly. After the sedimentation is completed the supernatant fluid is decanted. The remaining material is centrifuged. The precipitate, briefly dried, is suspended in from 5 to 10 cc. of physiologic solution of sodium chloride for each hundred cubic centimeters of urine and the suspension is violently shaken for a long time. After filtration the active principle is found in the filtrate, to which is added a few drops of 3 per cent tricresol and which is kept in the refrigerator. This filtrate is injected subcutaneously in rabbits weighing from 1,500 to 2,000 Gm. It is advisable to administer to the animals the solution of the precipitate corresponding to from 750 to 1,000 cc of urine. The injections are repeated for two or three days at least. The necropsy is performed two days after the last injection. The suprarenals of the rabbits treated were removed, dissected and fixed for several hours in Zenker's solution formalized 7 to 100. After embedding in petrolatum, sections from 5 to 6 microns thick are cut and colored simply with an erythrosin stain. In the cases of cancer subjected to the test the suprarenal cortex showed typical modifications. The fascicular zone is formed of cells the cytoplasm of which under physiologic conditions is filled with lipid inclusions. Liquefied by the histologic reactions, the latter leave the cytoplasm finely vacuolated and communicate to it a spongy aspect on which is based the term spongiocytes. Under the influence of cancerous urine however, the fatty vacuoles disappear, the spongiocytes diminish in volume and their cytoplasm takes on a compact and brightly staining appearance. The urine of healthy persons and persons suffering from acute and chronic diseases have so far failed to give the reaction. The author has also carried out some preliminary experiments with rabbits which indicate the possibility of the formation of antibodies in the blood of rabbits in the presence of the principle extracted from the urine of cancerous patients. The hypothesis must therefore be considered that this principle is a specific antigen.

**Expectoration of Tubercle Bacilli in Apparently Normal Children**—Faure and Matinier describe the cases of three older children who were expectorating tubercle bacilli but had no signs of tuberculosis. All the children possessed a true or suspected tuberculous heredity. The roentgenograms showed only the signs of ordinary sclerosis. Physical development was above the average, the first having gained more than 19 Kg in three years, the second 12 Kg in two years and the third more than 13 Kg in one year. Nevertheless they all expectorated tubercle bacilli without fever, functional or general

symptoms or auscultatory signs. The duration of positive sputum was approximately one month for the first child, two months for the second and eight months for the third. After considering various possible explanations for this condition, the authors state that they favor the hypothesis that these children were merely carriers of tubercle bacilli.

**Rapid Cholecystography with Epinephrine** — Zanetti suggests a modification of the cholecystography method of Antonucci. In order to simplify the method he proposes a subcutaneous injection of epinephrine to provoke hyperglycemia. A dose of 1 mg is sufficient to obtain a good "demonstration of load." To reinforce the action of the medicament one can administer from 80 to 100 Gm of sugar dissolved in a little water one hour before the injection, but this is not necessary. The shadow of the gallbladder appears two hours after the injection in healthy persons. Sometimes its appearance is delayed until the sixth or even the tenth hour. This delay has an important diagnostic value because it indicates a functional disorder of the liver or of the gallbladder which the usual normal cholecystography cannot reveal. Epinephrine also possesses the advantage of strengthening the patient against the dangers of collapse. The shadow of the bladder, although a little less distinct than that obtained by the usual methods, is nevertheless sufficient for a good roentgenologic demonstration. The author assigns three advantages to the use of epinephrine: (1) the early appearance of the vesicular shadow, (2) the possibility of studying the hepatic function, and (3) the possibility of differential diagnosis of gallbladder diseases. It has also the advantage of being simple and of practical use.

\*Characteristic Phenomenon of Gastric Ulcer. V. Bojovitch — p. 427

**Treatment of Central Pulmonary Hydatid Cysts** — Chavannaz thinks that it is unjustifiable to leave all central hydatid cysts of the lung alone. Although they often become cortical and may be operated on or stationary and relatively inoffensive or progress to the hilus and rupture and drain spontaneously along the natural passages, he feels that surgical intervention is often advisable. The operation by thoracotomy in a free pleura allows palpation of the lung and is less dangerous than puncture. After evacuation of the cyst and removal of the membrane as far as possible, drainage is indicated. As a rule, the bronchocutaneous fistulas following intervention heal spontaneously after a variable interval.

**Characteristic Phenomenon of Gastric Ulcer** — Bojovitch describes a condition of the abdominal wall in gastric ulcer which he believes is characteristic. In making the injections for local anesthesia, the needle always has difficulty in piercing the skin, which offers considerable resistance. In cutting the skin and adjacent aponeurosis in the epigastric region, the knife meets a special induration of these tissues. The leaves of the aponeurosis, once cut, separate like the edges of a cut cord in such a manner that difficulty is encountered in reuniting them by suture. The exact mechanism of production of this condition is doubtful but it appears that disorders of the nervous and circulatory systems of the stomach affect the skin and the abdominal layers and interfere with their nutrition.

**Histiocytic Elements in Blood Following Inoculations** — Frola found that inoculation of micro-organisms and various

dead bacterial bodies in guinea-pigs produced marked changes in the blood, such as neutrophilic polynucleosis, lymphocytopenia, monocytosis and histiocytoma. Live micro-organisms as differentiated from the dead bacterial bodies generally show a more important monocytic reaction. They are, above all, responsible for vacuolated elements in the circulation. Of the strains used, Flexner's bacillus, colibacillus and the diplococcus manifested great polymorphonuclear production, average monocytosis and poor histiocytosis, especially lymphocytoidemia and monocytoidemia. Eberth's bacillus, nonhemolytic streptococcus and scarlatinous streptococcus showed slight polymorphonuclear production and ordinary histiocytosis, generally of the lymphocytoids and monocytoids. The hemolytic streptococcus produces marked histiocytosis. The mobilization of histiocytic elements in the circulation differs according to the greater or lesser pathologic relation of the micro-organisms to the mesenchymal apparatus. Monocytic and lymphocytic elements found in the circulation at approximately the same age as young monocytes and monocytes of Rieder's type are due to an irritation of the mesenchymal tissue which, owing to the action of bacterial toxins, permits the passage of not fully matured elements into the circulation. The appearance of endothelial cells in the circulation only after particularly intensive treatments and at the acme of the disease, the rapidity of its appearance and disappearance, the presence of regressive lesions and the signs of a progressive histolysis help to establish that the endothelial cell is an expression of true exfoliation and a passage in the circulation of elements that have lost their normal characters and normal functions through lesions produced in the process of defense against infections. The study of mononuclear circulating elements is an important clinical sign in revealing the reactivity of the mesenchymal tissue. The monocytosis expresses a proliferative mesenchymal reactivity of normal evolution (hyperplasia of heterotypic evolution), the lymphocytoid and monocytoid elements in the blood indicate a proliferative reactivity of rapid evolution (hyperplasia of heterotypic evolution), and the endothelial elements point to diffuse degenerative mesenchymal lesions. The first follows stimulating lesions, the second mild toxic actions and the third serious toxic actions.

Pharmacodynamic Stimuli and Lactacidemia in Neurovegetative Dystonia. G. Benedetti — p. 334

Localization of Micro-Organisms in Kidneys After Ligation of Pedicle in Course of Experimental Bacteremia. N. Cirillo — p. 370

**Phylaxis** — Rubegni found that horse serum has a protective action against sparteine poisoning in keeping with the characteristics of the process of phylaxis in guinea-pigs and rabbits. The defense is relative, since some of the protected animals do not show resistance to the action of the poison and die. The phenomenon becomes manifest after six hours, reaches its maximum by eighteen hours, and is completely ended after thirteen days. The protection exercised by the serum against sparteine may be repeated at will, the animals are finally made to tolerate enormous doses of poison and simultaneously develop increased resistance to it and habit formation. The author does not believe that the sparteine treatment offers any protection against the anaphylactic shock of horse serum. If it does such protection is incomplete. The sparteine treatment combined with the injection of serum does not modify the production of antibodies and does not protect in any way against histamine intoxication.

Surgery in War Time. F. de A. Bergós Ribalta — p. 849

\*Muscular Chemism in Human and Experimental Diabetes. G. Marañón, J. A. Collazo and J. Almela — p. 852

**Muscular Chemism in Human and Experimental Diabetes** — Marañón and his collaborators state that by biopsy of the deltoid muscle in man and of the leg muscles of dogs deprived of the pancreas the muscular chemism in human and in grave experimental diabetes in dogs can be analyzed. The phosphagen content of the muscles is diminished in human

diabetes from 55.5 to 43.8 per cent, and in experimental diabetes from 61 to 39 per cent. Diabetic hypophosphagenia originates in a diminution of the glycogenic reserve, which induces the formation of phosphagen. Muscular glycogen falls from 676 to 422 mg per hundred cubic centimeters in diabetic persons and from 555 to 454 in diabetic dogs, as compared with normal persons and with normal dogs. The lactic acid content of the muscles, both in human and in experimental diabetes, varies within normal values. The differences are more accentuated when the calculations are based on the analysis of dry muscular substances. Water in the muscles is diminished in diabetes.

\*Elephantiasis Form of Neuropathic Edema. K. Horsch—p. 515.

**Neuropathic Edema**—Horsch reports an unusual form of edema in a woman, aged 27. It developed spontaneously on the back of the left hand and persisted for two years. Three years ago, spontaneous edema appeared on the back of the right hand and lasted three weeks. Seven years ago the patient developed an extensive edema of one of the legs, which persisted for three years. The patient was of a definitely psychopathic hysterical constitution. She exhibited a number of hysterical stigmas and symptoms, such as abnormal mental states, various paralyses and anesthetics. Under the influence of the method of treatment by psychic persuasion in combination with mechanical methods (suspension of the arm), the edema disappeared in the course of three weeks. The author thinks that this is not a pure form of edema which can be placed into one of the known groups. It belongs in all probability to the category of transient neuropathic edemas described by Quincke.

**Xanthomatosis with Cirrhosis of Liver**—Schilling emphasizes that xanthelasma with icterus differs in regard to the pathogenesis from the increased cholesterol content of the blood that exists in every obstruction icterus. If the hypercholesterolemia is produced by a chronic obstruction of the discharge of the bile, it disappears immediately after the stasis has been counteracted. However, in the icterus that concurs with xanthomas there is no obstruction that prevents the discharge of the bile, and in these cases the icterus is rather a retention icterus, caused by a change in the hepatic parenchyma. Thus the hypercholesterolemia is continuous in spite of the fact that the icterus may disappear or become reduced. Xanthoma cells, the so-called foam cells, may develop in all organs. The original appearance of these cells may become changed to such an extent that only a fibrogranulomatous scar remains. A knowledge of this transformation is of great importance for the clinician so that he may understand the pathogenesis of the severe organic disturbances that develop in the course of a xanthomatosis. If the xanthomatous changes occur only in the pancreas or liver, the disorder may present for years only the aspects of diabetes or of cirrhosis of the liver. Only an early examination of the blood, which will reveal an accumulation of the cholesterol, will give the clinician

an indication of the etiology of the disorder. The author reports the history of a woman he observed for two years. At first she had only a severe icterus and an enlargement of the liver, but in the further course large, flat xanthomas appeared in the face and on the abdomen. The examination of the blood revealed a cholesterol content of 657 mg per hundred cubic centimeters, 576 mg of free cholesterol and 81 mg of ester cholesterol. This shows that the cholesterolemia was caused by a retention of the free cholesterol, for the ester cholesterol showed normal values. Thus it is possible to differentiate two types of cholesterolemia, one in which the free cholesterol is increased and one in which the ester cholesterol is increased. By putting the woman on a diet that was free from animal cholesterols and contained only plant sterols, the cholesterol content of the blood could be gradually reduced, but the patient's general condition showed hardly any change. When the special diet was discontinued, the cholesterol increased again. One particularly painful tumor was removed. The patient died. The author believes that most cases of xanthomatosis are the result of disturbances in the elimination of cholesterol. If the liver is intact in this disease, the cholesterol is retained primarily in the ester form. However, in case of xanthomatous changes in the liver, the esterification of the cholesterol is deficient, just as in parenchymal hepatic changes of different origin.

**Method for Retarding Resorption of Insulin**—Thiel and his collaborators report experiments which prove that the resorption of insulin can be retarded by insulin gelatin mixtures. Suitable mixtures make it possible to prolong the resorption to such an extent that it becomes possible to give such large doses at once that, if they were given in the form of the aqueous solution, they would lead to severe hypoglycemic manifestations. The experiments prove further that it is possible to keep the blood sugar at an almost even level for a number of hours. This can be explained by an even resorption from an insulin depot. They hope this method will eventually make an insulin depot treatment possible and thereby dispense with the repeated daily injections. When the method is introduced into practice, it will be necessary to adjust the diet to the expected decrease in blood sugar, that is, to give the carbohydrates at the time of the maximal decrease. Further improvements will be necessary before the method is suitable for general practice. It is important to overcome the acid reaction of the gelatin and the painfulness of injection. Moreover, it has not been definitely decided as yet whether the best gelatin concentration is 10 per cent or whether a higher percentage will improve the conditions for the resorption of insulin still further.

Influence of Soap on Blood Within Vessels. G. Haselhorst and E. Mertens—p. 914.  
\*Alizarin in New Test for Gastric Secretion. B. Purjesz—p. 915.

**Convalescent Serum in Treatment of Poliomyelitis**—Schlossberger and Krumeich state that of 227 patients with acute anterior poliomyelitis twenty-six were treated with convalescent serum during the preparalytic stage, while the other 201 received the convalescent serum only after the paralytic symptoms had already developed. Among the twenty-six patients who received the serum during the preparalytic period there was not a single death, twenty-four recovered completely and only two developed paralytic symptoms. Of the 201 patients who received the convalescent serum after the development of the paralytic symptoms, 25 died and 148 showed no changes in the paralytic symptoms following the serum therapy, while in the other 28 the paralytic symptoms showed a more or less pronounced diminution. Since similar ratios

have been reported of poliomyelitic patients who received no treatment, the author is inclined to agree with other physicians who believe that after the paralytic symptoms have once developed the convalescent serum is no longer capable of counteracting them. During the preparalytic stage, however, the convalescent serum is the treatment of choice.

**Occult Hemorrhage from Stomach or Intestine**—Hulst states that two factors induced him to study the problem of occult hemorrhages: (1) the report of Boas according to which the stools of patients with carcinoma of the stomach or the intestine contain "occult hemoglobin" more often than do the stools of patients with occult hemorrhages of other origin, and (2) the recent observation that porphyrins occur in the oral cavity and in the bile of every person. The latter factor might become a source of error if blood is searched for in the feces according to Snapper's method, for in this method the porphyrins of the feces are determined by means of the spectroscope and then conclusions are drawn about the presence of occult hemorrhage. After showing that the mere presence of porphyrins in the feces is not sufficient for the determination of a hemorrhage, the author reports the results of tests made on feces of a large number of healthy persons who for a week were put on an exclusive milk and gruel diet, on the feces of thirty-eight patients who had a carcinoma of the stomach or the intestine, and on the feces of thirty-seven patients who had a hemorrhage of a different origin. He resorted to the benzidine test and searched for hematin, deuterohematin, coproporphyrin, deuteroporphyrin and protoporphyrin. He found that the feces of normal persons contain not only coproporphyrin but also frequently protoporphyrin. Among the thirty-eight cancer patients there were only eight in whom deuterohematin was not demonstrable and in the thirty-seven patients without cancer there was only one who had deuterohematin in the feces. The author concludes that the presence of deuterohematin, particularly if it can be demonstrated several times, is indicative of cancer of the stomach or the intestine. Moreover, he cites factors that make it probable that the "occult hemoglobin" of Boas is identical with deuterohematin.

**Alizarin in New Test for Gastric Secretion**—Purjesz points out that recently attempts have been made to devise tests for the secretory activity of the stomach which can dispense with the introduction of a stomach tube. Various organs (lungs, kidneys, liver and intestine) play a part in the maintenance of the acid-base equilibrium, and some investigators have resorted to the determination of the changes in the alveolar carbon dioxide tension as an indirect test for the gastric secretion. The author considers changes in the  $pH$  of the urine, which become manifest after a test breakfast, a more suitable indicator of the gastric secretion than the alveolar carbon dioxide tension. But since difficulties are encountered in the determination of the  $pH$ , it was decided to employ a substance that would indicate the changes by different shades of color. The patients were given a test breakfast of 0.2 Gm of the sodium salt of alizarin monosulphonate, 15 Gm of alcohol and 300 Gm of distilled water, because tests by other investigators had revealed that an increase of the  $pH$  above normal results in shades of red while a reduction below normal results in shades of yellow. In employing the test, the author did not control the degree of concentration by means of standard solutions but determined the  $pH$  in the same patient after an alcohol test breakfast without the alizarin as indicator. The test was made in the following manner: At 8 a. m. the patient had to evacuate the bladder completely. Then he was given the test drink and in the course of the following three hours urine specimens were collected at thirty minute intervals. The test was performed in patients having various degrees of acidity and it was found that from the intensity of the stain conclusions can be drawn as to the degree of acidity of the stomach. However, the author admits that the amount of mucus in the stomach as well as the specific gravity of the urine influences the color reaction. In persons whose stomach contains large amounts of mucus the red stain may fail to appear. He is convinced that test breakfasts with suitable indicators (alizarin) are helpful in the estimation of the secretory activity of the stomach.

Meincke Clarification Reaction II in Cerebrospinal Fluid F Weyrauch —p 804

**Autohemotherapy in Conditions of Depression**—After calling attention to Hauptmann's attempts at autohemotherapy in conditions of depression, Giehm cites explanations of its action mechanism. Vorschütz states that autohemotherapy results in an increase of globulins, which in turn exert their influence on the autonomic nervous system. The defibrinated blood is supposed to contain a substance that acts as a strong stimulus on the sympathetic. However, there is also the possibility that immunity processes are involved. The author reports his own experiences with autohemotherapy in twenty patients, ten of whom had a reactive depression, four an anxiety melancholia and six a circular depression. The blood was withdrawn from the vein of the arm and was immediately injected into the gluteal muscle. Every second day the patient was given from 3 to 15 cc of blood. The total number of injections was ten or twelve. Undesirable complications were never observed, but the reaction to the treatment differed considerably. Some patients developed a slight fever, in others the temperature remained the same, while still others experienced a reduction in temperature. The autohemotherapy was combined with quartz lamp irradiations. The patients were given exposures of from three to twenty minutes daily. As a rule the irradiations were given before the injections. Following the description of three cases, the author summarizes the results and reaches the conclusion that autohemotherapy is a valuable addition to the therapeutic armamentarium against psychic disturbances. It is particularly helpful in the treatment of reactive depressions in which physical symptoms predominate. Anxiety melancholias are likewise favorably influenced by it, but in circular depressions its efficacy is negligible.

**Organic Iodine Compound in Treatment of Goiter**—Misse and Sylla say that the cardiac symptoms of exophthalmic goiter are generally refractory to the ordinary methods of treatment. Digitalis, for instance as a rule does not become effective until after a preliminary iodine treatment. Since treatment with inorganic iodine involves certain dangers, an organic compound (3,5-diiodo-4-oxyphenylalanine) has been introduced into the treatment of exophthalmic goiter. This substance acts on the cardiac symptoms of exophthalmic goiter. Electrocardiographic studies during its administration revealed that changes are rare in case of a normal course of excitation. However, the originally strongly increased pulse rate decreases together with the annoying palpitation. The irritability of the sinus node becomes reduced under the influence of the organic compound but the sinus tachycardia occasionally remains uninfluenced in spite of clinical improvement. The high amplitude of the blood pressure generally decreases. The thyrotoxic disturbances in the cardiac rhythm are especially suitable for treatment with 3,5-diiodo-4-oxyphenylalanine. Auricular fibrillation responds particularly well. In far advanced cases the rapid and threatening form of fibrillation arrhythmia can often be transformed into the slower, less dangerous form. The administration requires individualization. In patients in whom the basal metabolic rate is increased by more than 60 per cent the authors give three times daily 0.1 Gm of the organic compound. In those with increases of from 40 to 60 per cent,

01 Gm is given only twice a day, and in those with lesser increases the dose is given only once a day. Medication with the beginning dose may be continued for three weeks. Then, after a pause of four days, somewhat smaller doses are given. The basal metabolic rate should be kept under constant control and the dosage should be adapted to the changes that ensue.

**Treatment of Acute Phosphorus Poisoning**—Liebscher says that in phosphorus poisoning the symptoms are not clear during the first few days. There is some vomiting, the vomit eventually being bloody, and some stupor. After three or five days, more serious symptoms become manifest. Jaundice and the signs of acute atrophy of the liver develop. The jaundice is of average gravity, the liver is contracted and sensitive to pressure, and there is spontaneous pain in the liver. The reactions for bile pigments are strongly positive in blood and urine, and leucine and tyrosine may be present in advanced cases. As a result of the accumulation of bile acids in the blood and of the failure of the liver metabolism, severe cerebral manifestations, such as somnolence, loss of consciousness, states of excitation and, finally, coma may develop, in the course of which death may result. A characteristic sign of phosphorus poisoning is fatty degeneration of the liver cells and lack of glycogen. The icterus is apparently hepatic, caused by impairment of the liver cells, and is not purely mechanical, as was assumed formerly. The treatment consists of irrigation of the stomach (even after ten hours), administration of animal charcoal, emetics, purgatives and excitants, and venesection with infusion of sodium chloride solution. However, the administration of fats, oils, milk and similar substances should be avoided on account of the solubility of the phosphorus. The prognosis is as a rule unfavorable, in spite of careful treatment, but the author describes a case in which a gradual improvement was noticeable. In this case a combination of dextrose and insulin and a strict diet proved effective in treating the hepatic disorders, but the symptomatic remedies were not neglected. The case proves that by careful attention to the liver the patient can be carried through the dangerous stage of the acute atrophy of the liver into a subacute stage and finally to recovery.

**Treatment of Menopausal Neuralgias**—Pisk found that the various forms of neuralgia (occipital, trigeminal, intercostal and sciatic and polyneuralgia) that develop in women of the menopausal age and are often refractory to the usual antineuralgic treatments may respond to treatment with follicular hormone. At first he administered the hormone by subcutaneous or intramuscular injection, but later he found that the oral administration was likewise effective. He reports his observations in twenty-one cases, of which fourteen were cured and kept free from relapse by a combination of antineuralgic and follicular hormone therapy (up to 2,000 mouse units daily). These cases had not responded to antineuralgic treatment alone.

**Syphilitic Stricture of Coronary Ostia**—Van Nuijden and Scherf point out that it is possible to differentiate various types of angina pectoris. They mention angina pectoris in coronary thrombosis or cardiac infarct, in coronary stenosis (exertion angina pectoris or Heberden's angina pectoris), in endocarditic or syphilitic insufficiency of the aortic valves (usually occurring at night and accompanied by increase in blood pressure), in paroxysmal tachycardia and in severe anemia. All these different types are characterized by special symptoms, so that differentiation is readily possible. Differentiation is important, because the various forms require different treatments and vary in their prognosis. All groups have in common not only the symptom of angina pectoris but also an important pathogenic factor, anoxemia of the cardiac muscle.

They differ only in the manner of development of the anoxemia. There is a sixth type of angina pectoris, a form of syphilitic mesoarteritis, in which the inflammation of the coronary ostia has produced a severe stricture. In this form, anginous disorders accompanied by anxiety develop after slight exertions. However, attacks of anxiety with crying and restlessness may develop also without pain. Increase in blood pressure is absent in this form of angina pectoris, and even a decrease in blood pressure has been observed. The authors discuss four cases of this type of angina pectoris. The cardiac action is not forceful during the attack. There is tachycardia and a soft, easily suppressible pulse, and the cardiac sounds are not accentuated. The restlessness and the anxious expectation of new attacks are especially characteristic in this type of patient. Clinical examination reveals nothing that is not also observable in mesoarteritis and in syphilitic aortic insufficiency. The electrocardiogram may be normal during rest, but following the slightest exertion the ST interval and the T wave are reduced and may become negative. The administration of nitrites is in general promptly effective in these cases and this differentiates them from coronary thrombosis, and the fact that the attacks develop not only after exertion or excitement but also during rest distinguishes them from classic or ambulatory angina pectoris. The prognosis of the angina pectoris caused by syphilitic stricture of the coronary ostia is unfavorable.

**Hypersensitivity to Liver Preparations**—Grun reports a case of hypersensitivity to parenterally administered liver preparations. Desensitization was accomplished by beginning with the injection of small doses and by gradually increasing them. The desensitization was of vital importance for the patient, because all other therapeutic measures failed and his life could not have been saved without the desensitization.

\*Serologic Studies on Chronic Action of Small Amounts of Carbon Monoxide P. Hofmann—p. 177

**Variation Experiments on Paratyphoid Group**—The experiments reported by Habs and Seitz were made to determine whether it is possible to effect in the bacteria of the paratyphoid group a transformation of the serologic structure that corresponds to the transition of one type to another. They employed the technique with which other experimenters had transformed pneumococci. First a rough form is obtained from the normal smooth form. Then a small quantity of the rough form is put into a culture medium that contains large numbers of killed bacteria of a different serologic type. The incubation in test tubes is followed by a transfer to agar plates, and the washed colonies are examined for their serologic structure. Systematic tests were carried out on a nonflagellate strain of the paratyphoid B group, because such a strain makes for the clearest experimental conditions, owing to the lack of flagella (H) antigens. The transformation into a rough form of considerable constancy was accomplished without difficulty. It proved possible to transform the rough form back into a smooth form. The serologic structure of the latter always corresponded to that of the original strain and thus it was merely a reversion into the original smooth form, a transformation into another type was not observed.

**Action of Saliva on Diphtheria Bacilli**—Dold and Weigmann studied the salivas of four healthy adults and of three healthy children for their action on genuine and virulent diphtheria bacilli (single culture material). It was found that the saliva of all persons after inactivation (by heating it for thirty minutes to 56°C) permitted an abundant growth of the

diphtheria bacilli, whereas the fresh saliva exerted a double influence (1) it inhibited the growth or killed the bacteria, (2) it transformed typical and virulent diphtheria bacilli (single culture material) into diphtheroids and further into pseudo-diphtheria bacilli. These actions of the fresh human saliva on genuine virulent diphtheria bacilli differed in intensity in the seven persons. It may therefore be assumed that, if a larger group of persons is examined, some will be found whose saliva produces these effects only slightly or not at all. The authors are of the opinion that these actions of the saliva on diphtheria bacilli are the cause of the pharyngeal and nasal immunity against diphtheria, which they were able to demonstrate in guinea pigs and monkeys that were susceptible to diphtheria toxin but did not develop symptoms of diphtheria. They believe that the behavior of the saliva toward diphtheria bacilli is at least of equal if not of greater importance than is the antitoxin content of the blood and tissues. This significance of the saliva, however, does not detract from the therapeutic value of diphtheria antitoxin.

**Chronic Action of Small Amounts of Carbon Monoxide**—Hofmann points out that, in order to determine whether a chronic carbon monoxide poisoning is possible numerous studies have been made on the immunity of animals that were under the influence of carbon monoxide. The results, however, were frequently contradictory, for some observers found that animals exposed to carbon monoxide poisoning more readily succumb to an infection, while others observed no disturbance in the mechanism of antibody formation. He made observations on rabbits and dogs that for about nine months inhaled daily for six hours 0.01, 0.03 or 0.09 per cent of carbon monoxide. He found that the rabbits were in good general condition during the entire period of observation. The resistance of the erythrocytes to hypotonic solutions of sodium chloride was unchanged in the dogs as well as in the rabbits. The alexin content of the serum of dogs and rabbits remained uninfluenced. The hemolytic complement in the serum of dogs increased during the first four weeks of exposure to carbon monoxide by from 75 to 100 per cent and remained at this level. An impairment of the formation of normal antibodies was not demonstrable under the influence of prolonged inhalation of carbon monoxide.

## Zeitschrift für Tuberkulose, Leipzig

Results of and Experiences in Incomplete Pneumothorax Treatment M Schlosser—p 322

Requirements of Efficacy of Phrenic Exeresis N F Bodungen—p 324

Tuberculous Ulcerations of Oral Mucous Membrane J Szanto—p 330

**Course of Tuberculosis and Function of Thyroid**—In a review of the literature, Schedtler shows that opinions about the significance of the thyroid in tuberculosis differ widely. He summarizes his experiments and clinical observations as follows: 1 In rabbits and guinea-pigs thyroidectomy seems to weaken the tuberculous infection. In rabbits the reduction in severity seems to be slightly less than that which is produced by castration. 2 Administration of thyroxine produces in guinea-pigs a more rapid course of the experimental tuberculosis. 3 Clinical observations on a larger material give no indication of regular relations between hyperfunction of the thyroid and the origin and course of tuberculosis. 4 Hypothyroid conditions likewise seem to exert no noticeable influence on the course of a tuberculosis. 5 The thyroxine therapy of tuberculosis still lacks reliable foundations.

**Tuberculous Symptoms During Menstruation**—Kriech describes an exacerbation in the tuberculous symptoms particularly an increase in fever, during the menstrual period of patients with certain forms of tuberculosis. He admits that during a normal menstrual cycle the impairments produced by this exacerbation are again repaired during the interval. However in certain types of tuberculous young women the menstruation becomes profuse and recurs after extremely short intervals later to be followed by an amenorrhea that has an unfavorable prognosis. If attempts are made to counteract

these menstrual disturbances with ovarian preparations, the fever and the general condition of these patients frequently take a turn for the worse. Since various dietary and medicinal treatments likewise failed, the author resorted to a symptomatic therapy and tried to check the severe menorrhea by giving three times a day fifteen drops of ergotamine tartrate. The result of this treatment was that the menstrual flow was reduced, the temperature curve became more regular and the other tuberculous symptoms improved, and with them the general condition.

**Phrenic Exeresis**—Bodungen says that phrenicectomy produces irreparable changes and often limits the respiratory resources of the patient. He considers an extensive application of phrenicectomy undesirable. The indications for it have to be evaluated carefully. In some cases phrenicectomy can be performed as the only intervention, in others it may be a complementary operation. Its efficacy is dependent (1) on the reduction in the volume of the thorax, (2) on the relative immobilization following the diaphragmatic paralysis and on the reduction in the mobility of the lower ribs, (3) on the changes in the lymph and blood circulations, and (4) on alterations in the sympathetic nervous system. Phrenicectomy is most promising in cases with a subacute or a chronic course, in which signs of reparation begin to appear, but attention must be given to the size of the cavity as well as to the surrounding pulmonary tissues. If the pulmonary pleura is free from adhesions or if the layers of the pleura are only slightly adherent, the results of phrenicectomy are favorable. For this reason the condition of the pleural sac should be carefully examined. Whenever cavities exist in the lower third of the lung, phrenic exeresis is preferable to artificial pneumothorax. Phrenicectomy is helpful as a complementary operation in cases of incomplete pneumothorax and also when filling of the pneumothorax is discontinued and there is no possibility of unfolding the lung. Phrenic exeresis can be done also for the purpose of retarding the course of a process or to make it less acute in cases in which a therapeutic result can no longer be expected and in which other interventions are not feasible. Phrenic exeresis is contraindicated in case of a cavern above a peripherally attached adhesion of the median lobe. A phrenic exeresis of the right side, previous to a thoracoplasty, prevents the horizontal collapse on account of the elevated position of the liver and should therefore not be performed unless it is absolutely necessary. In the pneumonic, bronchopneumonic and ulceropneumonic forms that take a rapid course, phrenicectomy is likewise contraindicated. The influence exerted by phrenic exeresis on the neighboring organs and on the heart has not been sufficiently explained as yet to permit its definite evaluation.

## Zentralblatt für Gynäkologie, Leipzig

58 1393 1440 (June 16) 1934

\*Eclampsia and Paralysis H Schwanen—p 1394

Hormone Menstrual Disturbances H van der Hoeven—p 1405

Lever Traction with Forceps K Holzapfel—p 1411

Rare Position of Legs in Head Presentation K Holzapfel—p 1413

**Eclampsia and Paralysis**—Schwanen points out that the high incidence of intracranial hemorrhages or of foci of softening in patients with eclampsia stands in marked contrast to the rarity of paralysis in the clinical manifestations of this disease. To determine the causes of this contrast, the author reviewed thirty-four cases from the literature and three of his own. He found the mortality of eclamptic paralysis extraordinarily high and the prognosis of eclamptic paralysis independent of the number of eclamptic attacks. The contrast between the high incidence of an anatomically demonstrable intracranial hemorrhage or softening and the rarity of a clinically demonstrable paralysis in eclampsia is traced to the following causes: 1 The eclampsia, in which apoplexy occurs, is usually so severe that it rapidly leads to coma and death, so that, so to speak, the patient does not live long enough to experience the paralysis. 2 Because of the severity of the eclampsia, the interest of the physician centers on the delivery and the circulation and so even if a paralysis could be neurologically demonstrable, it would not be detected, because the physician does not give his attention to neurologic disturbances. 3 Eclamptic paralysis particularly if it occurs without eclamptic attacks, frequently is not ascribed to eclampsia but rather

to embolism, intoxication or other factors. Since eclamptic paralysis is little known as yet, such an erroneous diagnosis is readily possible. The author advises neurologic control of every case of eclampsia and thinks that in this manner it will be possible to detect eclamptic paralysis more often. Eclamptic paralysis is frequently found in eclampsia without convulsions (twenty-one out of thirty-seven cases). It is to be assumed that the apoplexy interrupts the conduction tracts, so that convulsions can no longer be elicited. This explanation appears the more understandable in view of the cases in which eclamptic spasms develop only on the side that is not paralyzed. Convulsions and paralysis are both manifestations of eclampsia.

 High Vesicofixation According to Werth Halbrin. K. Heyrowsky — p 1541  
 Complete Vesical Inversion. N. P. Werhitzky — p 1543

**Ureteral Catheterization and Pyelitis of Pregnancy.**—According to von Mikulicz-Radecki, the concurrence of two factors is considered responsible for the development of pyelitis during pregnancy: (1) the presence of coli bacteria in the renal pelvis, which results in bacteriuria, and (2) urinary stasis. It has been assumed by Stoeckel that, as a result of the toxemia of pregnancy, the intestine and the ureters are in a state of atonia and that because of this the coli bacteria can pass the intestinal wall more readily and enter the renal pelvis by way of the blood stream. The ureteral atonia results in a deficient urinary discharge and in urinary stasis, it favors the multiplication of micro-organisms in the urine, the resorption of toxins and the invasion of micro-organisms into the mucous membrane. It is possible also that the atonic ureter is more readily compressed by the growing uterus. On the basis of these opinions about the pathogenesis, the author stresses the following aims of the treatment: removal of the stasis in the colon and with it the coli invasion by high enemas, destruction of the coli bacteria in the urine by bactericidal substances, removal of the urinary stasis by counteracting the ureteral compression by having the patient lie on the side that is normal, by increasing the urinary stream through the intake of large amounts of fluid by tonicizing remedies and finally by drainage of the renal pelvis that is, by ureteral catheterization. The latter procedure, with its possibilities for the drainage of the renal pelvis for continuous drainage and for irrigation of the renal pelvis, permits not only a more exact diagnosis but also a better treatment of the pyelitis of pregnancy. The author admits that ureteral catheterization does not always accomplish its aim for it may prove impossible to push the catheter all the way up into the renal pelvis, nevertheless it is effective in many cases. The obstruction is found most frequently in the subrenal ureteral loop, which is developed most noticeably during the second half of pregnancy. The author believes that by its bending this loop becomes the cause of a sudden urinary stasis in the renal pelvis, which in the presence of a bacteriuria leads to pyelitis and in case of sterile urine to a typical pain underneath the kidney.

**Transvesical Diaphanoscopy.**—The difficulties in the differential diagnosis of intra-abdominal tumors and the observation that during cystoscopy in the darkened room the urinary bladder lights up and is sharply demarcated against its surroundings induced Klaffen to utilize this light phenomenon of the bladder. This simple method not only gave information about the contents of cystomas but also revealed the antevesical position of the tumor and the downward placement, the shifting in other directions and the changes in the shape of the urinary bladder as the result of ovarian or other tumors. Further it permitted the differentiation between ovarian cystomas and ascites and, finally, it revealed the simultaneous presence of ovarian cysts and uterine myomas. The procedure is as follows: The urinary bladder is evacuated and irrigated with a 3 per cent boric acid solution until the fluid becomes clear. Then the bladder is filled with from 250 to 300 cc of a 3 per cent solution of boric acid and illuminated from within with an ordinary cystoscope. The examination is performed in a completely darkened room so that with the beak of the instrument

directed toward the vertex of the bladder, the organ becomes illuminated. If the abdominal wall is held tense in the region of the bladder, the light effect becomes clearer. It is also important that the patient be not too obese. Out of the total of 720 diaphanoscopic examinations, he cites several in which the growth was permeable for light and became illuminated. Then he describes some in which it was not permeable to light but in all of these cases the bladder was illuminated. There were some patients in whom the light from the bladder was cut off. Careful studies in these cases revealed that the shutting off of the light of the bladder resulted when a tumor, not permeable for light, prevented the filled bladder from rising above the rim of the symphysis and forced it downward into the small pelvis. Roentgenoscopy reveals the bladder in these cases, to be flattened and extended sideward. The author further describes his efforts to improve the technic of diaphanoscopy. He aimed to improve the light effect by the admixture of various substances to the fluid introduced into the bladder but these efforts failed. He also tried a combination of transvesical and transrectal examination, but this produced no improvement. However, it was observed that air filling of the bladder produced the same light effect in the bladder as did the boric acid solution. The marginal illumination of the bladder was even more intense when air was used. Efforts were made also to increase the intensity of the light, and they succeeded to such an extent that now a cystodiaphanoscope is available which furnishes from four to five times the amount of light as the older instrument. In discussing the mechanism of diaphanoscopy the author points out that it is due to the light reflection of the vesical mucous membrane. A portion of the light permeates the vesical wall and exerts the same effect on the tumor.

 Experiences with Pantocain Lumbar Anesthesia. O. Utter — p 478  
 \*Chylorhax. Case. L. Gronlund — p 439  
 \*Primary Sarcoma of Synovial Membrane of Knee Joint. Case. T. Hohenthal — p 458

**Chylorhax.**—In this case of effusion of chyle into the left side of the thoracic cavity, recovery without recurrence followed after eight punctures and the removal of 8,340 cc. of chylous fluid. Cancer of the stomach was neither clinically nor roentgenologically demonstrable. Trauma of the left side of the thorax had occurred three and a half years earlier. Although gastric cancer was established one and one half years later, Gronlund considers the etiology of the case doubtful.

**Primary Sarcoma of Synovial Membrane of Knee.**—Hohenthal's case in a young man presented a relatively benign course during a long period. Two years after a trauma of the right knee joint a slight tumor appeared at the seat of the injury, gradually growing larger. Two years later metastases were noted in the left upper arm. The following year the anatomopathologic picture indicated undoubted malignancy, and resection of the tumor of the knee joint and extirpation of the metastases were performed. Five years after the first symptoms metastases appeared in the right elbow and later in the region of the right shoulder, the left shoulder blade and on the anterior side of the left thigh, also recurrence in the right knee. Extirpation of the various tumors was done twice. Finally, eight years after the beginning of the disturbance, further metastases took place. The disease now progressed more rapidly, the general condition was aggravated, the tumor gradually metastasizing throughout the body, and death followed. Roentgenograms showed slight changes in the patella due to the primary tumor, in the diaphysis of the tibia there was gradually increasing clarification, which suggested a neoplasm infiltrating the bone tissue. The primary tumor, recurrences and metastases in general resembled one another, the histologic picture varying from spindle cell to round cell and polymorphous sarcoma. The motility of the knee joint was greatly reduced, the muscles of the leg atrophied. The author reviews the twenty-three cases of primary sarcoma of the synovial membrane of the knee joint reported in the literature. Recurrences were reported in three of these, and metastases in three.

## THE ENDURING ACHIEVEMENTS OF SIR CHARLES BELL

CHAIRMAN'S ADDRESS

HENRY W. WOLTMAN, M.D.  
ROCHESTER, MINN

For almost 2,000 years physiology of the nervous system had been at a standstill. Galen had wrought with such master strokes that the work seemed finished, or impossible of advancement. There existed a heritage that men were unwilling to dishonor.

In anatomy, progress had been more heartening. "Seven books on the structure of the human body" (1543) had broken the impasse, made possible an anatomic method of thinking, and laid the foundation of modern medicine. Unwillingly did Sylvius finally bend to the contentions of Vesalius with the remark, "Yes, man has changed, but not for the better."

Then there appeared a man with an idea, a man who left the revolving circle and showed the way to progress. The importance of this idea to physiologic investigations his magnificent contemporary, Johannes Müller, placed beside that of the discovery of the circulation of the blood by Harvey.

The salient events in the life of Charles Bell can be presented in a few words, for his career was singularly free from vicissitudes and, accordingly, no good biography of him has ever been written. He was born in 1774, in Edinburgh. His dissentient father, the Reverend John Bell, had severed his connection with the Episcopal Church to become a Presbyterian. His mother, highly intellectual and artistic, was never very well, nor very ill, during the eighty years of her life. She was, however, a devoted mother and, Bell said, his only teacher. Of the four sons, three achieved distinction: George Joseph, in law, and John and Charles in medicine.

John and Charles, while still very young, were taught by their mother to draw, and throughout life Charles cultivated this art, which, he said, "is necessary to many pursuits."<sup>1</sup> He also became an accomplished etcher, printer and modeler, and he used his art generously to illustrate his medical works (fig 1).

In Edinburgh, Charles studied anatomy under the tutelage of his brother John, who was eleven years his senior, and later with him became co-author of a textbook of anatomy, Charles writing the part that dealt with the nervous system. "The study of the nerves,"

Charles said, "is in truth the best foundation of medical knowledge." When his brother John attempted to gain for the younger surgeons the privilege of operating at the infirmary, the ensuing quarrel became a public scandal and closed the way to advancement for Charles. And so, in 1804, with £12 in his pocket, Charles left Edinburgh and embarked on a five-day journey by coach to London. Here he was received by Mr. Anthony Carlisle of Westminster Hospital with the observation "We like to manufacture our own raw material in London." Unperturbed and undismayed, he affiliated himself with the School of Great Windmill Street, founded by John and William Hunter.

"A man can surely do what he wills to do," says Schopenhauer, "but he cannot determine what he wills." Not so with Charles Bell. To carry forward the work of the Munros and the Hunters was not only his wish, it was his duty, he not only toiled industriously but with an all-consuming passion. Like the other Scots who invaded London, for it was an invasion, he achieved fame, and he shared their traits. "Their discoveries," Keith<sup>2</sup> says of these men, "were the only fortunes they designed for coming generations." In 1834, in his sixtieth year, Bell took the opportunity presented in making an address to remove a "very prevailing notion of the medical men in Edinburgh" that he was "pugnacious and sarcastic."<sup>2</sup>

Charles Bell had few intimates, but he was often seen at the theater and he was fond of music and of fly-fishing. He took pride in his appearance and was ever urbane in speech and in demeanor. He enjoyed teaching and had a good voice, he shunned prolixity and avoided Latin expressions when English served his purpose. Professionally, he was esteemed and he had a large practice. Although he avoided cultivating personal relationships with his patients, he treated them with tenderness, for example, he always sought to make a small incision, which he said was the most painful part of an operation. Corson quotes Roux the great French surgeon, who regarded Bell affectionately, as saying "Charles Bell is one of the few Englishmen who operates like a Frenchman, quickly and with grace, without affectation." When Bell's card was put in Roux's hand, it was "Ah! Sharley Bell! C'est lui-même!"<sup>3</sup>

In 1830, on the accession of William IV, he was made a knight of the Guelphic Order of Hanover. In 1836, after thirty-two years in London, he was appointed professor of surgery to the University of Edinburgh. In the last years he suffered from attacks of angina pectoris and he died during one of them in 1842, at the age of 68.

## BELL'S "IDEA OF A NEW ANATOMY OF THE BRAIN"

A moment ago I let fall a remark concerning an idea Bell tells us what this is in his "Idea of a New Anatomy of the Brain" Of the original 100 copies only two are known to remain, one in the British Museum and one in the Library of the Surgeon General of the United States Army Ebstein has provided us with a faithful reproduction of the original text<sup>4</sup>

In 1807 Charles wrote to his brother "My new anatomy of the brain is a thing that occupies my brain almost exclusively I hinted to you formerly that I was burning, or, on the eve of a grand discovery"

Bell wrote concisely and, on the whole, with remarkable clarity Since there has been some dispute as to his discovery that the posterior roots carry sensation, it is hardly fair to present excerpts from the already succinct statement of his "Idea" But let me present the salient points, as I see them, in Bell's own words and in the order in which he gave them

The prevailing doctrine of the anatomical school is, that the whole brain is a common sensorium<sup>4</sup> I have to offer reasons for believing that the cerebrum and cerebellum are different in function as in form, that the parts of the cerebrum

Fig 1—Bell's picture of opisthotonos A drawing by him of a patient with tetanus following an injury to the head sustained at the battle of Corunna (Obtained through the courtesy of Prof J R Learmonth of Aberdeen and published with the permission of the Royal College of Surgeons of Edinburgh and the Museum of Royal College of Surgeons of Edinburgh)

have different functions and that the nerves which we trace in the body are not single nerves possessing various powers, but bundles of different nerves, whose filaments are united for the convenience of distribution, but which are distinct in office, as they are in origin from the brain<sup>4</sup>

The external organs of the senses have the matter of the nerves adapted to receive certain impressions

The idea or perception is according to the part of the brain to which the nerve is attached

It is also very remarkable that an impression made on two different nerves of sense, though with the same instrument, will produce two distinct sensations, and the ideas resulting will have relation only to the organ affected<sup>4</sup>

Further, we can trace down the crura of the cerebrum into the anterior fasciculus of the spinal marrow, the crura of the cerebellum into the posterior fasciculus, I thought that here I might have an opportunity of touching the cerebellum, as it were, through the posterior portion of the spinal marrow, and the cerebrum by the anterior portion I found that injury done to the anterior portion of the spinal marrow, convulsed the animal more certainly than injury done to the posterior portion

Next, considering that the spinal nerves have a double root and being of opinion that the properties of the nerves derived from their connections with the parts of the brain I thought that I had an opportunity of putting my opinion to test of experiment and of proving at the same time that nerves of different endowments were in the same cord, and that they were together by the same sheath (fig 2)

On laying bare the roots of the spinal nerves, I found that I could divide across the posterior fasciculus of nerves, which took its origin from the posterior portion of the spinal marrow, without convulsing the muscles of the back, but that on touching the anterior fasciculus with the point of the knife, the muscles of the back were immediately convulsed Such were my reasons for concluding that the cerebrum and the cerebellum were parts distinct in function, and that every nerve possessing a double function obtained that by having a double root

The eighth nerve [in modern nomenclature N IX, N XI] is from the portion of the medulla oblongata which belongs to the cerebellum, the ninth nerve [now called XII] comes from the portion which belongs to the cerebrum The first is a nerve of the class called vital nerves, controlling secretly the operation of the body, the last is the motor nerve of the tongue and is an instrument of volition Nerves proceeding from the Crus Cerebelli go everywhere in seeming union with those from the Crus Cerebri, they unite the body together, and control the actions of the bodily frame and especially govern the operation of the viscera necessary to the continuance of life

The cerebrum I consider the grand organ by which the mind is united to the body Into it all the nerves from the external organs of the senses enter, and from it all the nerves which are agents of the passions pass out

We find that the several roots are distinct in their endowments, and are in respect to office distinct nerves

The nerves of sense, the olfactory, the optic, the auditory and the gustatory nerve, are traced backward into certain tubercles and convex bodies in the base of the brain An anatomist may say that the nerves of sense either form tubercles belonging to the base of the brain, or they enter into those convexities in the base of the cerebrum

As certainly as we discover an animal to have an external organ of sense, we find also a medullary tubercle

From the Crura Cerebri, or its prolongation in the anterior fasciculi of the spinal marrow, go off the nerves of motion

But with these nerves of motion which are passing outward there are nerves going inwards, nerves from the surfaces of the body, nerves of touch, and nerves of peculiar sensibility, having their seat in the body or viscera It is improbable that the tracts of cancerous matter, which we observe in the course of the medullary matter of the brain, are the seat of such peculiar sensibilities, the organs of certain powers which seem resident in the body

Herein Bell anticipates the later discoveries of cerebral localization He states clearly what is now referred to as "the doctrine of specific nerve energies" a phrase coined by Muller and to whom, and perhaps for this reason, this discovery is usually attributed although who assigns credit largely to Magendie, who did not mention Bell

Bell was very definite regarding the function of the anterior nerve roots, unfortunately he was not so specific regarding the function of the posterior roots One may infer, from what he says, that the posterior roots, the cerebellum and the visceral nerve supply each part of a closely knit system At the same time he spoke with positiveness regarding the different functions united in peripheral nerves, of cutaneous sensation, of a separation of function in the nerve root, and of the relationship of ganglions to sensation in a manner that might justify the inference that he regarded the posterior roots as being sensory in function He said later that this is what he meant and

<sup>4</sup> Bell Sir Charles Idea of a New Anatomy of the Brain London Strahan and Preston 1811 Idee einer neuen Hirnanatomie (1811) Originaltext und Uebersetzung mit Einleitung von Erich Ebstein Leipzig J A Barth 1911

that further prosecution of the subject required the introduction of medical cases

Bell attempted to set up an argument through inference, that is, by comparing the function of the spinal roots with the function of the sensory and motor components of the fifth cranial nerve, as determined by experiments on the fifth and seventh cranial nerves of man. That he did not parade his grand discovery, or he knew it was a grand discovery, and that he discontinued the original experiments on living animals, seems proof of his sincerity. That he should stop thinking on the subject is incredible.

Here the shadow of another great physiologist falls across our path. In 1822 Magendie, experimenting on a litter of eight puppies, severed the posterior roots of the lumbar and sacral nerves on one side. At the outset he thought that the limb corresponding to the divided roots was entirely paralyzed, but he later saw it move in a very evident manner, although its sensibility remained absolutely abolished. Then he cut the anterior roots, and he found the limb was completely immobile although it preserved an unequivocal sensibility.<sup>5</sup>

Magendie said he was unaware of Bell's work. Mr. John Shaw, Bell's student and brother-in-law, stated that he had visited Magendie in August 1821, had discussed Bell's views, and had repeated some of Bell's experiments. Evidently Magendie believed that both roots carry both motor and sensory impulses, but in different proportions.<sup>6</sup>

In 1831 Muller wrote "In a good physiological experiment, as in a good physical experiment, at every place, at every time, under the same circumstances, the same safe and unequivocal phenomena result, that cannot be said of the previous attempts to prove Bell's law. From the injury and general loss of power the error may be greater than the appearance of the results." Muller turned to frogs, which live a long time after the spinal column has been opened. The results of his experiments were convincing. The frogs seemed to remain well and hopped about cheerfully. "Irritation of the anterior roots with a galvanic current produces the strongest twitching. Galvanic irritation of the posterior roots never produces a trace of twitching." These results amazed him, for he thought that irritating the posterior roots would have some effect on the muscles. The conclusion, he says, is as sure as "two times two is four."

The "courteous and generous manner" in which Magendie dealt with Bell's claim to priority has been pointed out. Magendie complimented Bell on his ingenious ideas and said he had almost discovered the function of the spinal roots.<sup>7</sup>

Bell retorted, "Experiments have never been the means of discovery and a survey of what has been attempted of late years in physiology will prove that the opening of living animals has done more to perpetuate error than to confirm the just views taken from the study of anatomy and natural motions. Surely it is time that the schools of this kingdom should be distinguished from those of France. Let physiologists of this country borrow from us and follow up our opinions by experiments (see the experi-

ments of Magendie on the distinction in the roots of the spinal nerves) but let us continue to build that structure which has been commenced in the labours of the Munros and Hunters."

Magendie wrote (1830) "His [Bell's] investigative spirit, while a bit speculative, his great ability in the art of dissection, his rare talent in drawing, will always assure him a distinguished place among the anatomists of our time. But why should this teacher cast a shadow upon his works and upon himself in not giving justice where it is due? Why does he preserve this barbarous patriotism which repulses everything that does not come from his own country? Why does he pretend to discoveries which he has not made? Without a doubt, because it is his character, which it is not easy to change even if one may wish it." When Magendie announced some observations illustrating the principle of the specific dynamic action of nerves as his own, Bell asked, "Did you not tell us that you had a little English book in which this is written?"

Discovery of the motor and sensory functions of the fifth and seventh cranial nerves is also claimed by Bell. Waller gives Mayo unqualified credit for having

Fig. 2.—Drawing by Bell of his original dissection of the roots of the spinal cord (see parenthetical note to figure 1)

made these important distinctions.<sup>8</sup> Bell altered passages of previously published papers, in the publication of his textbook, to conform with the accumulation of more recent and more accurate data. This may have the "appearance of underhand dealing," as his critics claim, however it may occur without thought of deception. Bell may not always have acknowledged the laboratory source of his newer information, but it must be remembered that he was thoughtfully and assiduously accumulating clinical experiences which he was ever interpreting in the light of anatomy. Surgeons daily saw cases in which these nerves had been injured or in which they themselves had cut them. It seemed inconceivable to such a master anatomist as Bell that these things were not already known.

Time and again this dispute breaks out among the admirers of these two men, it delights readers who enjoy an intellectual skirmish and satisfies the participants, it is not yet settled nor will it be. Those interested will find what they seek though not the solution, in the *Lancet* 1911-1912, wherein Arthur Keith and

The mere acknowledgment of any untoward criticism in a brief review of a man's life always carries undue weight, and it may create the impression that Bell was a selfish, ruthless and unprincipled adventurer in the field of medical science. This he was not. As Don Quixote sagely remarked, "The great Homer wrote not in Latin, for he was a Greek, and Virgil wrote not in Greek, because he was a Latin." On occasion Sir Charles cut his pattern to fit his cloth, and the cloth was furnished by the times and its men.

#### BELL'S PALSY
